The current rate of progress is insufficient to achieve the three pillars of SDG7 by 2030.

Despite advances in electricity access, challenges of energy affordability and quality persist.

Improving energy efficiency is the most important enabler for sustainable energy.

The uptake and investments into renewable energy vary vastly across the UNECE region.

Indicators need to be revised to reflect the real imperatives of energy for sustainable development.
Global Tracking Framework:
UNECE Progress in Sustainable Energy

UNECE ENERGY SERIES No. 49
The designations employed and the presentation of the material in this publication do not imply the expression of any opinion whatsoever on the part of the Secretariat of the United Nations concerning the legal status of any country, territory, city or area, or of its authorities, or concerning the delimitation of its frontiers or boundaries.

Mention of any firm, licensed process or commercial products does not imply endorsement by the United Nations.
Foreword

The attainment of the sustainable energy targets in the 2030 Agenda for Sustainable Development (2030 Agenda) is not on track, either globally or in the United Nations Economic Commission for Europe (UNECE) region. Unless there is a significant acceleration of efforts and outcomes to ensure quality access to energy that is affordable and that meets the environmental, social, and economic imperatives of the 2030 Agenda, the international community will fall short of its ambitions and its commitments.

These are the blunt conclusions of the 2017 Global Tracking Framework report prepared by the World Bank and the International Energy Agency with the support of a host of organizations and UN agencies, including the five UN Regional Commissions. UNECE has cooperated with our sister Regional Commissions to prepare analyses for our respective regions and to elaborate a more detailed regional report as a complement to the global report.

The analysis for the UNECE region shows that progress differs from the global results, but that attainment in the region still falls short and solutions need to be adapted to national circumstances. Moving beyond the global results allows a more detailed assessment of national and regional conditions. While progress is insufficient in the UNECE region, the report presents case studies and examples showing that member States contributed significantly in proposing solutions to global problems.

There is not a single pathway to the future energy system, as each country has its own starting point and distinct options for how to proceed. It is essential for countries to develop their options, to consider both unilaterally and collectively how the objectives of energy for sustainable development might be achieved, and to establish an early warning system signalling if the objectives are likely not to be met. This report is a first step in that process, and a first alert has been issued.

This report sets forth the case for a holistic approach that countries must adopt to ensure a sustainable energy future that reconciles a tight emissions pathway with sustainable development aspirations. The approach will involve pursuing synergies and partnerships between low carbon alternatives and traditional fuels in terms of technology, policies, and market structure. Framework conditions are needed to mobilize investments that align with the objectives of the 2030 Agenda and that enable the needed transition. Rational economics and systemic improvements in efficiency throughout the energy chains lie at the heart of transformation to a sustainable energy system.

Decision-makers are offered a broader range of forward-looking indicators that cut across the 2030 Agenda from an energy perspective. Energy is intrinsically linked to the success of the 2030 Agenda, and progress needs to be tracked beyond SDG 7 across all energy-related goals.

Olga Algayerova
Executive Secretary
United Nations Economic Commission for Europe

This report was made possible through funding from the Sustainable Energy for All Initiative. Country data for SDG 7 indicators were provided by the World Bank and the International Energy Agency (IEA) and their partners. The World Bank oversaw the development of the five regional chapters within the 2017 Global Tracking Framework report. The production of this report was coordinated by UNECE. It could not have been prepared without the support of experts and reviewers from across the UNECE region.

Lead authors: Robert Tromop, Lisa Tinschert

Supplementary authorship:
Stefanie Held, Michal Drabik, and Harikrishnan Tulsidas of the UNECE Sustainable Energy Division. Further support was provided by Annukka Lipponen and other staff from the UNECE Environment Division, as well as Ilona Gremminger (Universität St. Gallen).

Contributors and Reviewers:
Through virtual consultation and exchange taking place between 12 December 2016 and 15 July 2017, responses were received from the following reviewers: Mariela A. Stefanllari, President, Human Environment Culture Foundation, Albania; Olga Dovnar, Deputy Chairperson, International Cooperation Unit, National Statistical Committee, Belarus; Andrei Miniankou, Head of Department, Department for Energy Efficiency, State Committee on Standardization, Republic of Belarus; Aleksandr Snetkov, Head of Industrial Statistics Department, National Statistical Committee, Belarus; Vladimir Zui, Professor, Belarusian State University, Belarus; Valentina Ilieva, Official, Energy Strategies and Policies for Sustainable Energy Development Directorate, Ministry of Energy, Bulgaria; Zlatko Pavicic, Independent Expert, Croatia; Matija Vajdic, Senior Researcher, Energy Institute Hrvoje Pozar, Croatia; Sigurd Heiberg, Chairperson, Petronavit A.S., Norway; Margalita Arabidze, Head of Energy Efficiency and Renewable Energy Division, Ministry of Energy, Georgia; Anna Sikharulidze, Technical Manager, Sustainable Development Centre Remissia, Georgia; Gogita Todradze, Deputy Executive Director, National Statistics Office, Georgia; Dr. Dr. h.c. Manuela Troschke, IOS Institute for East and Southeast European Studies, University of Regensburg, Germany; Vincent Duijnhouwer, Associate Director, Product & Business Development – Energy Efficiency and Climate Change Team, European Bank for Reconstruction and Development, Russian Federation; Hannes MacNulty, Development Manager, Sustainable Energy Solutions, BG Consulting and Engineers, Switzerland; Tahmina Mahmud, Independent Expert, Tajikistan; and Maksym Chepeliev, Research Economist, Center for Global Trade Analysis, Department of Agricultural Economics, Purdue University, United States of America (for Ukraine), Denis Hicks Director / Management Advisor, High Delta Limited, United Kingdom of Great Britain and Northern Ireland.
In addition, the following UNECE country representatives participated in the technical workshop organized by ESCAP in Bangkok, Thailand on 16 January 2017: Hayk Harutyunyan, Deputy Minister, Ministry of Energy Infrastructures and Natural Resources, Armenia; Vugar Jabbarov, Adviser, Ministry of Energy, Azerbaijan; Margalita Arabidze, Head of Energy Efficiency and Alternative Energy Division, Ministry of Energy, Georgia; Bekbergen Kerey, Deputy Director of Department of International Cooperation and Economic Integration Processes, Ministry of Energy, Kazakhstan; Aleksey Ponomarev, Vice President, Industrial Cooperation and Public Programs, Skolkovo Institute of Science and Technology, Skolkovo Innovation Center, Russian Fed.; and Ulugbek Agzamov, Head of Division of the Department for UN and International Organizations Affairs, Ministry of Foreign Affairs, Uzbekistan.

A workshop on “Tracking Progress on Energy for Sustainable Development: Data and Indicators” was organized with the other Regional Commissions at the launch of the global 2017 GTF report in Astana, Kazakhstan on 14 June 2017 with participation of the following stakeholders: Olga Dovnar, Belarus; Mikhail Malashenka, Vice Chairman of the Committee Director of the Department, State Committee for Standardization Department for Energy Efficiency, Belarus; Andrei Malochka, Chief of Department of General Energy, State Enterprise Beltei, Belarus; Andrei Miniankou, Belarus; Ina Yeliseyeva, Head of Information and Analysis Section, Department for Energy Efficiency of the State Committee on Standardization, Belarus; Gogita Todradze, Deputy Executive Director, National Statistics Office of Georgia (GEOSTAT); Hamid Sherwali, Chairperson, Libyan Authority of Renewable Energy, Libya; Ahmad Saleh Abdelkarim Karaki, Project Management Unit, PRCS Hebron, Palestine; Oafa Quteineh, Electrical Engineering Technical Department, HEPCO, Palestine; Dr. Hazir Farouk Abdelraheem Elhaj, Head, Biofuel Research Group, Aeronautical Research Centre, Sudan; Ahmed Muna, Agricultural Technology Transfer Society, Sudan; Nafaa Baccari, Deputy Director of Renewable Energy, ANME, Tunisia; Dhamir Mannai, Executive Director, Mannai Energy, Tunisia; Professor Nickolas J. Themelis, director of the Earth Engineering Centre, Columbia University and chair of the global WTERT Council; Claire Morel, Statistics Programme Manager, IEA for EU4Energy, International Energy Agency, France; Kim Roseberry, Consultant, Energy Security and Water Resources Section, Environment and Development Division, UN ESCAP; Radia Sedaoui, Chief, Energy Section, Sustainable Development Policies Division, UN ESCWA; Mongi Bida, First Economic Affairs Officer, Energy Section, Sustainable Development Policies Division, UN ESCWA.

Executive Summary

If the world is to develop in line with the 2030 Agenda for Sustainable Development, it will be necessary to ensure access to affordable, reliable, sustainable, and modern energy services while reducing greenhouse gas (GHG) emissions and the carbon footprint of the energy sector. The Sustainable Development Goal for energy (SDG 7) has three principal objectives: ensure universal access to modern energy services; significantly increase the share of renewable energy in the global energy mix; and double the global rate of improvement in energy efficiency.

Unfortunately, the energy sector’s support for the 2030 Agenda is at risk of faltering. On global scale the current pace of progress toward the SDG 7 targets will not meet 2030 targets. Energy is crucial to the success of the 2030 Agenda and there is a clear imperative for profound and immediate changes in how energy is produced, transformed, traded, and consumed of the objectives of the 2030 Agenda are to be attained. The rate of improvement in energy efficiency, the deployment of net low carbon energy solutions, and the provision of sustainable access to modern energy services are insufficient. Concrete measures are needed to improve energy productivity, rationalize energy use, optimize energy resources, and deploy sustainable energy technology and infrastructure.

This report has been prepared by UNECE to complement the global analysis presented in the third edition of the Global Tracking Framework (2017 GTF), published by the World Bank and its partners. It explores the global findings in a regional context to offer further insights into regional developments, projects and concerns. Already the 2017 GTF results are a wake-up call for greater effort on a number of fronts. Increased financing, bolder policy commitments, and a willingness to embrace appropriate technology on a wider scale are urgently needed. This is no different in the UNECE region with its 56 member States located in the northern hemisphere. While examples for progress exist, overall countries need to accelerate their efforts, as there remain only 12 years to meet the 2030 Agenda.

This UNECE regional report point to the extraordinary potential that the UNECE region offers with regards to energy efficiency and renewable energy development and deployment, but notes as well the regions reliance on fossil fuels.

Attainment of the objectives of SDG 7 in the UNECE region.

Attainment of the objectives of SDG 7 is falling short in the UNECE region. While many of the energy challenges in this region are similar to those elsewhere in the world, the region has specific climatic, economic, environmental and political circumstances and the implications are found in inefficient use of energy, power cuts, increasing energy costs, and unsustainable and unaffordable heating in winter. Interpreting the global data on a regional basis has led to valuable insights about country contributions and needs.

FIGURE 1: Summary of Attainment of Sustainable Energy Targets in the UNECE Region.
At present, some countries export large quantities of fossil fuels as part of their economic model and feature some of the world’s highest levels of energy intensity. The number of countries and the number of people whose national incomes and livelihood depend on fossil energy is important and will remain so over the outlook period. This feature has consequences for attainment of SDG 7 across the region.

➢ Global Target: Universal access to electricity and clean cooking fuels and technologies: 100% in 2030

Although the region has universal household electrification in terms of physical access, ageing infrastructure, a lack of supply diversity and increasing tariffs lead to poor power quality and, for some, energy poverty. This situation is particularly acute during the cold winter months in the Northern hemisphere, and disproportionately affects poor and rural populations. As a result, some consumers have reverted to local sources of solid fuels for cooking and heating, and others to electricity with off-grid diesel generators.

Further, human comfort and safety depend on substantial heating services in most UNECE countries. This dependence is not reflected in the statistics on electricity network access. A significant challenge exists to upgrade older, uninsulated housing stock with locked-in fossil fuel dependence. Low-income households throughout UNECE make tradeoffs between heat, food, and other needs, and there is a measurable proportion of households that spend more than 10% of their income on energy. Addressing greenhouse gas (GHG) emissions without improving energy efficiency would worsen energy poverty. The region achieved 98% access to clean fuels and technology for cooking in 2014, up from 95% in 2000, but 23.3 million people in remote regions still relied on traditional fuels for cooking in 2014.

➢ Global Target: Double the rate of improvement in energy efficiency: -2.6% per year (Compound annual growth rate - CAGR)

The region achieved an aggregated energy intensity of 5.1 MJ/USD in 2014, with wide ranges at the sub-regional level from 3.7 MJ/USD in Western and Central Europe to 7.2 MJ/USD in Caucasus, Central Asia, Eastern Europe and the Russian Federation. The growth rate from 2012-14 was -2.0% per annum, almost equal to the global rate of -2.1%. Decomposition analysis shows that changes in energy intensity since 1990 result from decoupling energy consumption from economic growth through efficiency gains.

Energy intensity changes differed across sectors. While energy intensity in the industry and agricultural sector declined continuously between 1990 and 2014, the residential and service sector showed only modest declines in 2012-2014 (-0.9% and -0.4%, respectively) after a sharp decline in 2010-2012 (-3.1% and -3.4%, respectively).

Most countries in the region have developed National Energy Efficiency Action Plans but show limited progress in their implementation. Improving building energy performance is slow, though there has been solid appliance efficiency progress in North America and the European Union. A largely untapped potential for industry energy productivity improvement exists across the region. With the exception of the member countries of the European Union, vehicle fuel economy is not progressing.

Efficiency in fossil fuel power generation is another important indicator as improving conversion efficiencies would reduce the inputs (coal, gas, and oil) required to produce the same electrical output. In the UNECE region, average fossil fuel power plant efficiency improved from 36% in 1990 to 41% in 2014, compared to a lower global rate of 39%. The improvements in supply side efficiency in electricity generation in the region were driven primarily by investment in high efficiency combined cycle gas turbines, while the overall number was dampened by continued use of less efficient coal-fired power plants. Average gas-fired generation efficiencies in the region improved from 37% in 1990 to 49% in 2014, the highest globally. Electricity transmission and distribution losses declined from 8.2% in 1990 to 7.2% in 2014 (8.9% globally), the least among all world regions, while natural gas transmission and distribution losses fell from 1.2% to 0.6%.

➢ Global Target: Significantly increase the share of renewable energy in total final energy consumption (TFC): 36% in 2030

The UNECE region was the only region in the United Nations system to increase the share of renewable energy in TFC from 2012 to 2014 to 11%. The reasons for this outcome include strong support mechanisms. In addition, the increased application of more flexible market-based support mechanisms such as auctions, the overall decrease of installation costs, and increased awareness of the feasibility of renewable energy projects across most of the region all contributed.

While growth of renewable energy output in the region accelerated over the period, progress on sub-regional level varied significantly. Looking beyond the share of renewable energy in TFC, a more detailed picture emerges. Taking the share of renewable energy in total primary energy supply (TPES), for the UNECE region as a whole, renewable energy from wind, solar, and geothermal accounted for only 1.6% of TPES in 2014. If hydropower, biofuels and waste are included, this figure rises to 9%, compared to a global share of 14%. The numbers show that modern renewable energies are still lagging. Solar and wind power had a share of 2.1% in TPES in Western and Central Europe, the highest share among UNECE sub-regions.

Investments in 17 countries from the Caucasus, Central Asia, Eastern and Southeast Europe and the Russian Federation fell from USD 700 million in 2013 to USD 400 million in 2015,
Sustainable energy needs to be tracked differently, more holistically

There is no common view in the UNECE region nor globally of what sustainable energy is or how to attain it. Apart from the global challenges regarding the implementation of the 2030 Agenda and other pledges that countries have made, countries in the UNECE have divergent economic development, resource availability and energy mixes embedded in today’s national energy strategies. As a consequence, multiple national approaches and outcomes can be found. Choices must be economically and socially rational for each country and be made in the broader context of an economy as a whole. The integration should consider quality of life.

From a mere tracking progress on SDG 7, this report has moved towards tracking progress beyond SDG 7. It has become evident in the preparation of this report that the current approach would benefit from refinements. Relevant indicators should reflect a holistic approach and address the challenges that countries face as systems become more complex and needs more urgent. Taking such a holistic approach leads to the application of a broader concept of “energy for sustainable development” which seeks to measure progress towards all energy-related SDGs to reflect the cross-cutting interconnections among the SDGs.

This report highlights the high dependence on fossil fuels of many countries of the UNECE region, combined with a high carbon-intensity of the energy sector. Therefore, tracking the rate of fossil fuels in the energy mix in addition to the existing indicators will provide useful information about the real state of transformational systems change. To assess if targets linked to SDG 13 on climate can be achieved, it would be useful to provide information on the carbon intensity of the energy sector. As mentioned above, SDG 7 targets 7A and 7B need to be monitored closely to track mobilisation of funding, investment in energy efficiency, and foreign direct investment in infrastructure and technology.

Current indicators have been derived from the existing data gathering and reporting infrastructure that emerged from the energy system of the past. In order to inform policies to accelerate the transition to an energy system that can meet the 2030 Agenda objectives and targets, it will be necessary to develop appropriate indicators for the system of the future, adapt data gathering systems and build the required capacities to collect, analyse, track and report new data and indicators.

Practical solutions from countries show a changing face of energy

Each country sets its national energy strategy based on its unique perspective, so multiple national approaches and outcomes are found. Country case studies included in this report highlight the changing face of energy towards a service industry. For example, to address energy poverty, the United Kingdom introduced a community led programme to develop renewable energy for self-sufficiency (case study 5). To improve appliance energy efficiency, Turkey fostered market transformation by introducing legislation for minimum energy performance standards (case study 8). The potential of solid biomass and its increased application for combined heat and power (CHP) generation is highlighted for Croatia (case study 15), while Germany’s introduction of auctions for off-shore winds provides insights towards the shift to economically feasible applications of variable renewable energy (case study 16). Also addressed in this report are the (Intended) Nationally Determined Contributions ((I)NDCs) by UNECE member States to address climate change mitigation challenges (case study 20), as well as case studies from Poland and the Ukraine on the recovery of coal seam methane (case study 21).

The existing infrastructure, including the physical, regulatory, policy, and organizational infrastructure of the energy industry, is shaping policy approach and national energy decision making. There is evidence in the UNECE region of challenges in heating service affordability, reliability of aging systems and future resilience needs. Truly transforming the energy system will require a creative shift in policy and regulation to unleash innovation, investment, and improved energy productivity. Yet, in many countries in the region, the current political, regulatory, and industrial infrastructure is not yet ready for such a transformation.

Moving ahead: Key challenges for the UNECE region

- **Energy security**: These concerns impede improvements in technical, environmental, and economic efficiency, but can be interpreted in different ways. Some countries and sub-regions seek to promote energy independence or self-sufficiency while others strive for efficient integration of energy markets. Promoting mutually beneficial economic-interdependence would accelerate attainment of the 2030 Agenda through integrative, nexus areas that the notion of sustainable development offers. For energy, it is critical to think in terms of a wholly interconnected, complex system in which supply, demand, conversation, transport and transmission interact freely and flexibly.

- **Fossil fuel dependency**: Fossil fuels dominate the region’s energy mix and underpin today’s energy access and economic development. The locked-in dependency on fossil fuels is neglected in conversations about energy
efficiency and renewable energy, which slows attainment of objectives. The TPES of UNECE countries is just over 80% fossil energy. Less than half the fossil energy used to generate electricity is converted to usable energy, with the remainder lost during conversion. Even under a climate change scenario that meets a 2°C target, fossil energy will still represent 40% of the energy mix in 2050. The underlying tension between achieving SDG 7 and the impact on other SDGs is immediately apparent.

➢ Climate commitments: Given the regions dependence on fossil fuels, meeting the 2030 Agenda’s climate objectives must be integrated with the remainder of the agenda to achieve the aspired decarbonisation of future energy systems. Integrated solutions require clear understanding of the climate-related impacts of energy in connection with the development-related opportunities that energy represents. The two most relevant GHGs from the energy sector are CO2, mainly from the combustion of fossil fuels, and methane (CH4) emissions along the coal and gas value chains. This report suggests three additional indicators to track progress towards a less-carbon intensive energy sector: GHG intensity of TPES, GHG intensity of TFC, and per capita GHG intensity of energy. The UNECE region also is falling short on these relevant indicators.

➢ Constrained optionality: Certain options for improving the overall performance of today’s energy system are excluded in the formulation of some national sustainable energy strategies for reasons of public perception, politics, imposed market distortions, or legitimate but possibly solvable concerns of safety or environment. These options include nuclear power, carbon, capture, use and storage (CCUS), shale gas, natural gas in transport, among others. Including them in the future would change potential to meet the 2030 Agenda.

➢ Energy as a service, not energy as a commodity: The energy industry has succeeded in raising quality of life around the world, most notably in the advanced economies but even in the developing world. The energy industry today is a commodity business in which players earn returns by producing and selling more. The existing infrastructure, including the physical, regulatory, policy, and organizational infrastructure of the energy industry, is shaping decisions about the future inasmuch as today’s structures are expected to persist in the future. And yet consumer energy services are inadequate. There is evidence in the UNECE region of challenges in heating service affordability, reliability of aging systems and future resilience needs. What is needed for true sustainability is to reconceive the energy industry as a complex of service industries. Such a reconfiguration would unleash innovation, investment, and improved energy productivity. Truly transforming the energy system will require a creative shift in policy and regulation, yet in many countries the current political, regulatory, and industrial infrastructure is not yet ready for such a transformation.
I. Introduction

The third edition of the Global Tracking Framework (2017 GTF) assessed progress on the three pillars of sustainable energy: energy access, energy efficiency, and renewable energy. The findings in this report clearly portrayed that the pace of progress on meeting the objectives and targets of the 2030 Agenda on Sustainable Development (2030 Agenda) is falling well short of what is needed to meet global objectives by 2030.

The 2017 GTF provides regional analyses of progress on sustainable energy that delve into regional trends to explain the global results and to highlight individual country experiences. The regional analyses were prepared in collaboration with the five United Nations Regional Commissions (UNRCs): the Economic Commission for Africa, ECA; the Economic and Social Commission for West Asia, ESCWA; the Economic and Social Commission for Asia and the Pacific, ESCAP; the Economic Commission for Europe, UNECE; and the Economic Commission for Latin America and the Caribbean, ECLAC.

This report has been prepared by UNECE to complement the regional analysis presented in the 2017 GTF to explore the global findings in a regional context, to consider alternative and additional data sources that may offer further insights into regional concerns, and to reflect on alternative indicators for a more robust assessment of progress toward energy for sustainable development in the future.

The report takes a system perspective on energy in the UNECE region. It highlights interconnections along the energy value chain, and explores the policies and pricing mechanisms that shape the ability to deliver society’s energy needs. Energy is undergoing a paradigm shift away from the commodity business that society has been comfortable with for two centuries. The human needs for comfort, health, shelter, mobility and the like are more properly thought of as services. It is the demand for these energy services that leads to investment throughout the energy value chain from delivery to transformation and ultimately development of primary energy resources. A reorientation of the energy industry from commodity production to service provision will drive the innovations and efficiency improvements that are at the heart of the 2030 Agenda.

The challenges faced by all governments are to understand which policy choices and options can deliver improved sustainability, consumer utility, productivity and economic resilience in their energy system and to connect these efforts to the greening of their economies. The adoption of a holistic and cross-sectoral approach to energy policy-making will enable synergies with other sectors, and integrate energy-water-food nexus benefits. This report explores these issues and highlights successful applications of best practices.

This report is not intended to present a complete dataset for all proposed indicator categories. The interpretation of data on regional and sub-regional level shows the need to develop regional and country-specific solutions. A broader perspective on energy for sustainable development is further required to measure success more comprehensively and point out more specifically the challenges for the diverse UNECE membership.

1.1. Sustainable Energy and the Sustainable Development Agenda

On 1 January 2016, the 17 Sustainable Development Goals (SDGs) of the 2030 Agenda for Sustainable Development (2030 Agenda) officially came into force.

The SDGs call for action by all countries to promote prosperity while protecting the planet. They recognize that ending poverty goes hand-in-hand with economic growth, addressing social needs, and tackling climate change and environmental protection. They are also inter-related in that achieving one goal invariably impacts on one or more of the other goals.

If the world is to develop in line with the 2030 Agenda, it will be necessary to ensure access to affordable, reliable, sustainable, and modern energy services while reducing energy’s environmental footprint. Energy is crucial to the 2030 Agenda. It is the golden thread that weaves together all our aspirations and implies an imperative for profound and immediate changes in how energy is produced, transformed, traded, and consumed.

Energy is a fundamental need as it provides the essential services of modern life including cooking, heating, cooling, lighting, and mobility. It enables the operation of appliances, information and communications technology (ICT), and machines in every sector of every country. Doctors use energy to provide healthcare services in clinics, it provides lighting for children to study, and when it is unavailable women (most often) are obliged to gather wood to burn for cooking (which then degrades indoor air quality).

“Sustainable energy” is about providing the energy services that promote sustainable development of a country. Energy was not included explicitly as one of the Millennium Development Goals but has assumed a prominent place in the 2030 Agenda. SDG 7 - the energy goal - aims to ensure access to affordable, reliable, sustainable and modern energy for all, and links sustainability in energy to the other 16 goals.
Energy for Sustainable Development

SDG2: Zero Hunger
- Decoupling economic growth from environmental degradation by reducing environmental footprint of energy
- Resource and consumption efficiency along energy value chain

SDG8: Decent Work and Economic Growth
- Reduction of energy sector GHG emissions
- Climate resilience of energy infrastructure
- Sustainable energy policies and strategies
- Financing sustainable energy

SDG12: Responsible Consumption and Production
- Sustainable use of energy resources
- Circular economy approaches for waste and energy management
- Phase-out of fossil fuel subsidies
- Awareness raising for energy saving / efficiency

SDG13: Climate Action
- Public-private energy partnerships
- Energy technology transfer
- Regional & international energy cooperation
- Capacity development

SDG7: Affordable Clean Energy
- Access to affordable, reliable and modern energy services
- Increase share of renewable energy
- Improvement in energy efficiency
- International cooperation and investment in sustainable energy research, technology, and infrastructure

SDG6: Clean Water and Sanitation
- Improved water use efficiency in the energy sector
- Reduction of thermal pollution of waters
- Improved cooperation for integrated water resource management across borders for hydro projects

SDG11: Sustainable Cities and Communities
- Resilient and sustainable energy infrastructure and resource use
- Energy technology development and adaptation

SDG1: No Poverty
- Sustainable transport fuels
- Sustainable energy supply for cities
- Sustainable and resilient urban energy infrastructure

SDG4: Quality Education
- Improved water use efficiency in the energy sector
- Reduction of thermal pollution of waters
- Improved cooperation for integrated water resource management across borders for hydro projects

SDG5: Gender Equality
- Access to affordable, reliable and modern energy services
- Increase share of renewable energy
- Improvement in energy efficiency
- International cooperation and investment in sustainable energy research, technology, and infrastructure

SDG10: Reduced Inequalities
- Decoupling economic growth from environmental degradation by reducing environmental footprint of energy
- Resource and consumption efficiency along energy value chain

SDG14: Life Below Water
- Access to affordable, reliable and modern energy services
- Increase share of renewable energy
- Improvement in energy efficiency
- International cooperation and investment in sustainable energy research, technology, and infrastructure

SDG15: Life on Land
- Decoupling economic growth from environmental degradation by reducing environmental footprint of energy
- Resource and consumption efficiency along energy value chain

SDG16: Peace, Justice and Strong Institutions
- Access to affordable, reliable and modern energy services
- Increase share of renewable energy
- Improvement in energy efficiency
- International cooperation and investment in sustainable energy research, technology, and infrastructure

SDG17: Partnerships
- Public-private energy partnerships
- Energy technology transfer
- Regional & international energy cooperation
- Capacity development

SDG3: Good Health and Wellbeing
- Access to affordable, reliable and modern energy services
- Increase share of renewable energy
- Improvement in energy efficiency
- International cooperation and investment in sustainable energy research, technology, and infrastructure

SDG18: Peace, Justice and Strong Institutions
- Access to affordable, reliable and modern energy services
- Increase share of renewable energy
- Improvement in energy efficiency
- International cooperation and investment in sustainable energy research, technology, and infrastructure

SDG9: Industry, Innovation and Infrastructure
- Access to affordable, reliable and modern energy services
- Increase share of renewable energy
- Improvement in energy efficiency
- International cooperation and investment in sustainable energy research, technology, and infrastructure

SDG19: Peace, Justice and Strong Institutions
- Access to affordable, reliable and modern energy services
- Increase share of renewable energy
- Improvement in energy efficiency
- International cooperation and investment in sustainable energy research, technology, and infrastructure

FIGURE 1.1: Mapping of Energy-Related Sustainable Development Goals.
SDG 7 has five targets:

7.1 By 2030, ensure universal access to affordable, reliable and modern energy services,

7.2 By 2030, increase substantially the share of renewable energy in the global energy mix,

7.3 By 2030, double the global rate of energy efficiency improvement,

7.A By 2030, enhance international cooperation to facilitate access to clean energy research and technology, including renewable energy, energy efficiency and advanced and cleaner fossil-fuel technology, and promote investment in energy infrastructure and clean energy technology,

7.B By 2030, expand infrastructure and upgrade technology for supplying modern and sustainable energy services for all in developing countries, in particular least developed countries, small-island developing States, and land-locked developing countries, in accordance with their respective programmes of support.

The targets focus on renewable energy, energy efficiency and access without addressing fossil fuels or nuclear. The targets also do not connect to nexus-sectors (e.g., climate, food, water, or agriculture).

1.2. “Energy for Sustainable Development” in the 2030 Agenda

While the SDG 7 targets are central to energy’s role in the 2030 Agenda, a broader perspective on the contribution energy will make to sustainable development is needed. Energy considerations are important for attainment of many of the SDGs, and a wide set of indicators is needed for the broader picture.

Figure 1.1 maps how Sustainable Energy underpins the 2030 Agenda. SDG 7 should not be seen in isolation but as enabling the attainment of the wider set of SDG goals with improved energy productivity, lesser emissions and sustainable access to energy services. The figure highlights those SDGs with higher relevance for “energy for sustainable development”. Beyond the direct link with SDG 7, a particularly strong relationship exists with two further goals: SDG 9 and 13. Without the supply of affordable and clean energy these SDGs cannot be achieved. A progressively complex relationship exists with other SDGs, notably SDGs 2, 6, 8, 11, 12 and 17. The success of the remaining SDGs is either indirectly linked to energy, or energy acts as an enabler. As the success of one goal depends on another, a complex system of dependencies emerges. This complexity is crucial to understand in assessing progress to sustainable energy, and to develop global, regional and national solutions to attain the set targets.

1.3. A System Perspective on Sustainable Energy

National energy systems are complex, inter-connected networks that require well-developed policies to function efficiently. The current energy system needs to change significantly to provide affordable energy services, to achieve security of supply and to reduce greenhouse gas emissions. This shift requires deployment of affordable low-carbon technologies and energy efficiency measures, the costs and benefits of which are often highly uncertain.

Moreover, energy systems consist of stakeholders who often have conflicting objectives. The actors and their technologies interact through physical and social networks governed by institutional and political structures whose evolution is also uncertain. Agenda 2030 imposes additional externalities on the energy system, increasing the complexity and uncertainty inherent in policy development.

Figure 1.2 provides a simplified overview to the energy system with its inter-connected parts. Inefficiencies in each stage of the value chain wastes energy. Efficiencies achieved throughout the chain reduce costs for consumers. Typically demand for energy services is moderated by competitive offers, the costs of technology, cost-reflective prices and clear information. The demand to improve energy efficiency is driven by a need for both improved or increased service and the need to manage energy costs.

FIGURE 1.2: A System Perspective on Energy Sustainability.
Chapter I: Introduction

Energy efficiency policies and measures deliver both improved services and a reduction in demand for energy; the balance between these is based on consumer’s utility-maximising response to the energy efficiency intervention.

This approach improves the adaptability and resilience of the energy system with a diversity of distributed and centrally supplied energy as well as off-grid energy supplies consumers. The supply system (primary energy production, transformation, generation, and transmission / transportation) and its capacity to adapt to changing environmental pressures, technology and resource options, will drive investments in both demand and supply. The result should be an improvement in the supply, reliability and costs of energy.

1.4. UNECE Region Overview

The UNECE region is important in the global energy picture. In 2014, the region accounted for 42% of the world’s GDP, 40% of the world’s total primary energy supply (TPES), and 34% of the world’s CO₂ emissions from fossil fuel combustion.

The UNECE region is very diverse. It comprises 56 countries with a total population in 2015 of 1.3 billion people, representing 18% of the world’s population and the majority of the Northern Hemisphere (see figure 1.3). The seven UNECE sub-regions include Caucasus, Central Asia including Turkey, Eastern Europe including Israel, Southeast Europe, North America, the Russian Federation, as well as Western and Central Europe.

The diversity of the region is shown by its history of economic development and the ranges of size of country, population density, national income, climate and access to indigenous energy sources.

The UNECE region has been shaped predominantly by the reconstruction and development that followed World War II that established the infrastructure and technology that persists in today’s energy, industrial and transport systems. The development resulted in a level of industrialisation and technological progress ahead of other regions but also created an enduring legacy that is the starting point for future evolution.

Almost half a billion people live in Western and Central Europe, with another 356 million people in North America. The remaining third of the UNECE population resides largely in the Russian Federation (144 million) and Central Asia (including Turkey, 146 million), Eastern Europe has 67 million people. The smallest sub-region in terms of population is the Caucasus with 16 million.

Population density per km² varies widely across the region. Iceland and Canada have low population densities (3.3 and 3.9 people per km², respectively), whereas San Marino (530 people per km²), Malta (1349 people per km²), and Monaco (18,865 people per km²) have much higher densities.

In terms of GDP per capita, Western and Central European countries enjoy the highest per capita GDP, for example, Luxembourg (USD 101,449 (current), Switzerland (USD 80,945), and Ireland (USD 61,133). The countries of Caucasus, Central Asia, and Eastern Europe have much lower per capita GDPs including Tajikistan (USD 926), Kyrgyzstan (USD 1,103), and Moldova (USD 1,848).

The climate in the UNECE varies from Mediterranean in the South, to Arctic in the North.

For energy supplies, some sub-regions are net energy importers, such as Western Europe, while other, such as North America and the Russian Federation, are net energy exporters.

This diversity across the UNECE region results in countries having different policy priorities based on wealth and perception of affordability of policy options, climate, availability of energy resources and the stage of economic development.

A more complete set of socio-economic data for the region are presented in Annex I, Table A.1.
FIGURE 1.3: Map of 56 UNECE member States and Sub-Regions used in this Report.
II. Tracking Sustainable Energy Progress in UNECE

2.1. Overview

On a global scale, the current pace of progress on the SDG 7 targets (universal access to electricity, growth in the share of renewable energy and improvements in energy intensity) will not meet the objectives of the 2030 Agenda targets:

- **The rate at which people are getting access to electricity is slowing.** While UNECE officially has achieved 100% access to power networks, there remain significant quality and affordability challenges. Issues related to access to alternative energy networks such as natural gas also need to be considered.

- **It is estimated that annual renewable energy investments need to double or triple in order to achieve the 2030 target.** Even though the UNECE region is the only region with an increasing share of renewable energy in TFC, sub-regions with extremely low and declining investment rates remain a challenge.

- **Only energy intensity improvements have been progressing towards objectives,** with global energy savings during the 2012-2014 GTF reporting period enough to supply Brazil and Pakistan combined. **Nevertheless investments in improvements in energy efficiency will need to increase by a factor of 3 to 6 in order to achieve the 2030 target.**

The 2017 GTF results are a wake-up call for greater effort on a number of fronts, including increased financing, bolder policy commitments, and a willingness to embrace new technologies faster and on a wider scale.

2.1.1. Energy in the UNECE Region

The following sections give an overview of the energy situation in the UNECE region, including information on its energy mix, energy trade, and infrastructure.

Figure 2.1 shows the share in the UNECE sub-regions of global TPES as compared to the rest of the world in 2014. The UNECE region uses 39% of global TPES. North America has the main share (18% globally), followed by the 33 countries of Western and Central Europe with 12%.
Each country’s TPES, energy intensity (TPES/capita), and “own production index” are shown in Annex II, Table A.2. The Own Production Index is calculated by dividing total energy consumed in a country by that produced from TPES. It is a simple indication of a country’s energy balance: below 1 represents a net energy importer and above 1 represents a net energy exporter. A country can increase its index by reducing energy use by improving energy efficiency or economic restructuring or by increasing energy production. A summary of the countries with the highest and lowest own production index values in the UNECE sub-regions is provided below (Table 2.1). The table shows that the different UNECE sub-regions vary significantly between net energy importers and exporters. Norway has a high index of 6.2 due to its high domestic use of hydropower and significant oil exports, followed by Azerbaijan. Azerbaijan’s oil exports result in an index of 4.1.

The sub-regions Eastern Europe, Western and Central Europe, and Southeast Europe are net energy importers. Over the past decade, North America has gradually increased its exports, so that it is expected to become a net exporter between now and 2025, mainly due to the reduction of petroleum liquid imports and the increase in natural gas exports. The Russian Federation, and Central Asia sub-region are net energy exporters.

The Caucasus sub-region became a net energy exporter in 1998, mainly driven by Azerbaijan’s oil and gas exports. Georgia and Armenia have an index below 1.

Figure 2.4 highlights the own production index values. Countries with an index over 1 are shaded blue, while countries with an index below 1 are shaded orange. Western, Central, Eastern and Southeast Europe which are all net importers with the exception of Norway. Within Central Asia, Kyrgyzstan and Tajikistan are net importers, even though the sub-region is overall an energy exporter.

Regional Energy Infrastructure

UNECE member States have a complex network of interconnected energy infrastructure and trade. Figure 2.5 shows the natural gas distribution system in Europe, including the gas trade infrastructure across the Caspian and Black Sea region. The map highlights the issues of trade routes that cross multiple borders, with significant flows of gas from the Russian Federation to Europe. In 2013, 39% of gas imports to the countries of the European Union came from the Russian Federation; followed by Norwegian gas with 31% (year 2012). In order to diversify gas supply for countries in Central and Southeast Europe, the Southern Gas Corridor is currently being built, with operations expected to commence in 2019-2020. It aims to expand infrastructure for gas to be supplied to the EU from the Caspian Basin, Central Asia, the Middle East, and the Eastern Mediterranean Basin. Expected gas supply is in the range of annually 80 to 100 bcm of gas.
With growing energy trade with Asia, the energy infrastructure in the region is extending towards the East. Figure 2.6 shows the natural gas and oil pipeline infrastructure going eastwards from Central Asia.

The 3,666 km long Central Asia – China natural gas pipeline, built in several phases between 2003 and 2014 brings gas from mainly Turkmenistan, but also Kazakhstan and Uzbekistan, to China. By 2015, Turkmenistan exported

**FIGURE 2.5:** Natural Gas Distribution System in Europe and the Commonwealth of Independent States (CIS).

![Natural Gas Distribution System in Europe and the Commonwealth of Independent States (CIS).](image)

Source: SManalysis (2009).

**FIGURE 2.6:** Central-Asia China Gas Energy Infrastructure.

![Central-Asia China Gas Energy Infrastructure.](image)

Source: Strafor (2013).
40 billion m\(^3\) per year to China, which is set to be increased to 65 billion m\(^3\) per year. China is further receiving 10 billion m\(^3\) per year from Uzbekistan, and 5 billion m\(^3\) Kazakhstan. From 2009 to 2015, Turkmenistan has already delivered 125 billion m\(^3\) gas to China.\(^{16}\)

Most of the natural gas that was previously exported to the Russian Federation is now going east. As a result, the 1960 to 1980s built infrastructure connecting Central Asia with Russian Federation, the 4,495 km long "Central Asia Centre" gas pipeline, is now heavily under-utilized.\(^{17}\)

A majority of the existing power infrastructure in the Eastern stretches of the region date back to the early era of the former Soviet Union. Within Central Asia most of the existing power related infrastructure, including generation and transmission networks, is in disrepair or inefficiently operated. More than 77% of Kazakhstan’s and 87% of Kyrgyzstan’s power generation assets are at least 20 years old. The share of old equipment older than 20 years is 86% and 88% for Tajikistan and Uzbekistan, respectively.\(^{18}\)

A summary of indicators used in the 2017 GTF including core indicators\(^{20}\).

Data presented here focus on the period from 1990-2014, including an interpretation of the tracking period 2012-2014. Many developments have occurred since 2014 and new trends may have emerged in the last three years. The interpretation of data in a regional context has led to introduction of additional data in this report. The intent is to enrich the analysis of progress for SDG 7 and to initiate a discussion on a broader set of indicators to track energy for sustainable development across the 17 SDGs.

A summary of indicators used in the 2017 GTF including information on the methodology is provided in Annex III. The list is complemented by recommendations from stakeholder consultations to provide the basis for further discussion on indicators to track energy for sustainable development in Annex V.

### 2.2. Progress across SDG 7 Targets

The following sections present indicators and data for the three SDG 7 targets on energy efficiency, renewable energy, and energy access.\(^{19}\) Indicators and data from the 2017 GTF report included in this presentation are complemented with additional information beyond the core indicators\(^{20}\).

Energy efficiency is defined as the relationship between the energy consumed and the output (energy service) produced by that energy. Increasing energy efficiency means using either less energy to provide the same output, or use the same amount of energy to produce more.\(^{22}\) For example, it can be used on micro-level to express efficiency of energy in a sector, such as steel, as well as on product level, such as the energy efficiency of applications, or in terms of energy efficiency in power generation such as from coal, gas and renewable energy.

Energy efficiency is an enabler for many policies: reducing the energy required for economic output in the context of the capital, labour and other material resources in an economy improves energy productivity. Since a report by McKinsey it has been recognised as a low-hanging fruit to achieve global goals and targets, nevertheless implementation of energy efficiency measures could be improved.\(^{23}\)

A commonly used measure for energy efficiency is energy intensity although the two are not equivalent and energy intensity, in itself, does not account for differing economic structures, availability of resources, activity levels or climatic drivers for energy use. Energy intensity is an indication of how much energy is needed to produce one unit of economic output. Lower ratio indicates that less energy is used to produce one unit of output. It is usually an indicator used on macro-economic level, defined in terms of energy rather than output.\(^{24}\)

For example, high energy intensity may directly result from a country extracting and exporting energy intensive mineral products in a cold climate (e.g., Canada, Sweden, or the Russian Federation), and low intensity from high levels of service industries (e.g., Switzerland). In neither case does energy intensity offer insights into the underlying efficiency of the economy, historical development paths, and improvements in energy efficiency, or the opportunities for further energy efficiency improvements.

**SDG 7 Indicator: Energy Intensity of Total Primary Energy Supply to GDP; Compound Annual Growth Rate (CAGR) of Primary Energy Intensity** \(^{25}\)

Primary energy intensity is the ratio of TPES to GDP measured at Power Purchasing Parity (PPP) in constant 2011 USD (MJ/2011 PPP USD). Energy intensity in the region has been improving since 1990. Over the period 1990-2014, primary energy intensity\(^{26}\) declined at the fastest rate globally (1.9% (CAGR), from 8.0 MJ/USD to 5.1 MJ/USD in 2014 (see figure 2.7)\(^{27}\)). From 2012 to 2014, the UNECE region avoided 3.9 exajoules (EJ)\(^{28}\) of TFC – about a third of avoided energy globally, and nearly equivalent to the 2014 TFC of Spain and the Czech Republic combined. The decline

---

14
of energy intensity within the tracking period was -2.01%, almost equal to the global rate of 2.1% but short of the 2.6% needed over 2010-2030 to meet the targets of SDG 7.

Energy intensity by economic sector

Energy intensity in the UNECE region has declined across all sectors. In the industrial sector, energy intensity declined continuously across all periods. Energy intensity in the agricultural sector improved in recent years, dropping by 6.4% annually. Energy intensity in the services sector and the residential sectors dropped significantly from 2010-2012 before returning to more modest trends from 2012-2014.

Decomposition of energy end-use trends considers three main components over time: activity change, sectoral structure shifts, and the energy efficiency improvements. In the UNECE region there has been a relative decoupling of energy consumption from GDP growth in the region, which began in the early 1990s, as GDP increased and energy demand remained stable (see figure 2.8).

Sub-Regional Energy Intensity Trends

Energy intensity has been declining in all sub-regions from 1990-2014, and the declines accelerated over the tracking period 2012-2014 except in North America (see figure 2.9) where the rate of decline slowed recently. There is a wide variance of energy intensities across the region from 18 MJ/USD in Iceland with its high reliance on geothermal energy to about 2 MJ/USD in Switzerland with a large services industry and hydroelectric power.

North America had the third highest energy intensity in 1990 at 8.8 MJ/USD, which fell to 5.8 MJ/USD by 2014 as economic growth decoupled from energy demand. In 2010-12, the pace...
of improvement accelerated, driven by cost-reflective energy prices and energy efficiency policies. In the power sector, the shift to natural gas enabled efficiencies in new electricity and heat plants that displaced older coal-fired plants. Yet activity in energy-extractive industries recorded significant growth. Canada’s cold climate and mineral extraction industry resulted in energy intensity of 7.7 MJ/USD, higher than the United States’ 5.6 MJ/USD.

In **Western and Central Europe**, energy intensity also declined continuously between 1990–2014, from 5.5 MJ/USD, the lowest in the region, to 3.7 MJ/USD. This was driven by a combination of cost-reflective energy prices and consistent, comprehensive, and aggressive energy efficiency policies and commitments. The European Union’s Renewable Energy Directive 2009/28/EC set an energy efficiency target for 2020 of a 20% reduction in energy demand relative to a business-as-usual projection. All member countries of the European Union were mandated to shape National Energy Efficiency Action Plans (NEEAP) requiring durable efficiency improvements along the whole energy value chain. These plans should largely achieve the 2020 targets, in part due to the global financial crisis.\(^3\) The European Union’s 2020 target was originally set at 18.6% below projected primary energy consumption of 1,542 Mtoe (64 EJ), but primary energy consumption was revised downward to 1,527 Mtoe (63 EJ).\(^4\)

Higher-productivity countries in Western and Central Europe reported very low energy intensity, but Iceland’s was the highest in 2014 as its economy featured high energy-intensive aluminium smelters and a primary energy resource of low grade geothermal energy with high transformation losses.

In **Southeast Europe**, sharp improvements in energy intensity were made in the 1990s when conflict in Croatia, and Bosnia and Herzegovina caused energy demand to drop faster than economic output. During the 2000s, innovations in productivity contributed to further improvements. The pace of energy intensity improvements in Southeast Europe picked up in 2012–14, and energy intensity reached 4.6 MJ/USD in 2014, on the back of underlying structural shifts to lower-intensity services and recovery of GDP to 2008 levels. Still, significant annual variations in energy intensity suggest that the sub-region has yet to implement firm policies on cost-reflective energy prices and energy efficiency.

The sub-region’s northern neighbours have more challenging climates but often have lower energy intensity, pointing to further scope for energy efficiency action in Southeast Europe. Energy intensity in Southeast Europe is converging slowly toward the levels in the rest of Europe.

In **Caucasus, Central Asia, Eastern Europe, and the Russian Federation** energy intensity declined between 1990–2014 from 12.5 MJ/USD - the highest in the region – to 7.2 MJ/USD. As in Southeast Europe, variations suggest that prices and policies have still to mature into durable drivers. Changes in structure lie beneath the reported changes in many countries. In Tajikistan, for example, the declining trend was interrupted in 2011, and energy intensity increased as industries grew following long stagnation after the 1992–97 civil war. Israel’s energy intensity was low in 2014 (3.7 MJ/USD) as was Turkey’s (3.5 MJ/USD) as both benefited from low-energy-intensity industries and mild climates.

Most countries in the sub-region still have energy intensities above 5MJ/USD. Limited policy action, monitoring and evaluation, and data and compliance, coupled with energy price subsidies, slowed gains after 1998.

**Additional Indicator: Supply Side Efficiency in Electricity Generation**

Supply side efficiency (calculated as generated power output / primary energy input) in electricity production in the region improved from 36% in 1990 to 41% in 2014 – despite the improvement more than half the primary fossil energy used.
to generate electricity is wasted. This improvement was driven primarily by investment in high efficiency combined cycle gas turbines, which improved overall gas-fired generation efficiency from 37% to 49% over the period. Transmission and distribution losses dropped from 8.2% in 1990 to 7.2% in 2014, reaching the lowest levels in the world. Natural gas transmission and distribution losses decreased from 1.2% to 0.6% during the same period.

2.2.2. Renewable Energy

SDG 7 Indicator: Share of Renewable Energy in Total Final Energy Consumption

The UNECE region was the only UN region that consistently increased its share of renewable energy in the mix over the tracking period 2012-2014, and the rate of growth recently accelerated. It was also the only region to report flat growth in TFC over the period 1990-2014. The share of renewable energy in TFC increased from 6% in 1990 to 11% in 2014, with growth fastest in Southeast Europe (see figure 2.10). The share of modern renewable energy reached 11%, the second highest globally, as traditional biomass consumption is negligible in the region.

Initially, the development of hydroelectric power underpinned a high rate of electricity access in the region. More recently, renewable energy developments have been for the most part in large wind and solar farms, reflecting a central supply focus and falling production costs.

Within the UNECE region, most investments in renewable energy occurred in Western Europe and North America as a result of strong price supports and policies such as Feed-in Tariffs (FiTs), auctions and tax incentives.

Within renewable energy sources, the share of modern solid biofuels consumption was the highest in 2014 at 38%, followed by hydropower at 28%, and modern liquid biofuels at 14%. In 2012-2014, wind and solar power production grew fastest, reaching shares of 9.5% and 4.3% respectively.

Sub-Regional Renewable Energy Trends

As shown in Figure 2.9, all sub-regions showed an increasing share of renewable energy, albeit from a very low base.

- **North America** reported the second lowest share of renewable energy in 2014 in the region at 10%. In 2014, over half of renewable energy came from modern biofuels, and another 26% from hydropower. Between 2012 and 2014, wind and solar power reported the strongest growth, reaching shares of 9.2% and 2.5% respectively.

- In **Western and Central Europe**, the share of renewable energy in TFC increased from 7.3% in 1990 to 17% in 2014. Individual country’s FiT schemes and the European Union’s Renewable Energy Directive 2009/28/EC supported strong growth in installed renewable energy capacity. For those countries that are members of the European Union the 2009/28/EC Directive mandates a binding aggregate target that 20% of energy use be provided from renewable energy sources by 2020. The Directive also sets a target of 10% for renewable energy use in transport by 2020.

The objectives are to be met through measurable national targets and policies set by each country. Countries have set individual targets with some choosing more ambitious 2020 national targets, such as Denmark (30%), France (23%) and Portugal (31%), while others remain below the 20% target of the Directive, such as the United Kingdom (15%), Germany.

---

**FIGURE 2.10:** Growing Renewable Energy in all UNECE Sub-Regions (Share of renewable energy in TFC, in %).

Data Source: IEA and UN Statistics, quoted from World Bank et al. (2017a).
(18%), and the Netherlands (14%). Overall, the targets range from 10% (Malta) to 49% (Sweden). According to latest data from EuroStat, in 2015 the 28 member countries of the European Union achieved a 16.7% share of TFC, up from 8.5% in 2004. Based on assessments by the European Environment Agency, the European Union is on track to meet its aggregate 2020 target. From the Western and Central Europe sub-region, the Czech Republic (13%), Estonia (25%), Finland (38%), Italy (17%), Lithuania (23%) and Sweden (49%) already have achieved their set targets.

For the whole Western and Central Europe sub-region, over half of renewable energy consumption in 2014 came from modern biofuels and another 23% from hydropower. Since 2010, wind and solar power reported the strongest growth, reaching shares of 11% and 5.6%, respectively, in 2014. Iceland, Norway, and Liechtenstein reported the highest shares of renewable energy use, at 76%, 62% and 57%, respectively. Iceland and Norway have long histories in hydropower and geothermal energy, and Liechtenstein leads globally in solar photovoltaic energy per capita.

In each case the high share of renewable energy is driven by the availability of the resource, commitment of the government and willingness of society as a whole to bear the costs of the transformation. In the case of Norway, it shows that setting ambitious national targets can drive a high share of renewable energy (the 2020 target is 67.5%).

Southeast Europe reached 26% of renewable energy in TFC in 2014, the largest share in the region, with over half in traditional biomass. Montenegro, Bosnia and Herzegovina, and Albania, reported the highest shares of renewable energy in TFC, at 46%, 42% and 39%, respectively. Southeast Europe also has the largest share of hydropower in the region, led by Romania, Croatia and Serbia. In 2012-2014, wind and solar power production showed the strongest growth, reaching 8.0% and 3.3%, respectively, of TFC. Similar to countries in Western and Central Europe, some of the countries are driven by the European Union’s Directive 2009/28/EC, including Bulgaria (16%), Croatia (20%), and Romania (24%). All three countries have achieved their set 2020 targets in 2015 already.

The Caucasus, Central Asia, Eastern Europe, and Russian Federation sub-regions presented the smallest share of renewable energy in TFC in the region, at 4.9% in 2014, and investments in the sub-region were focused largely on hydropower. Modern solid biofuels accounted for 20%, having decreased sharply between 1990 and 2014. Hydropower dominated the renewable energy mix with a 62% share in 2014, led by Tajikistan. In 2012-2014, liquid biofuels and wind power recorded the strongest growth, reaching 0.7% and 7.0% shares, respectively. Ukraine reported the fastest growth in wind power in the sub-region, almost doubling the share of wind power in TFC from 16% in 2010 to 29% in 2014.

Data Source: IEA and UN Statistics, quoted from World Bank et al. (2017a).
Chapter II: Tracking Sustainable Energy Progress in UNECE

Data Source: IEA World Energy Balances; UN Statistics.

Figure 2.11 summarises the share of modern and traditional renewable energy for each country, and the rates of change between 2012-2014.41

Additional Indicator: Share of Renewable Energy in Total Primary Energy Supply

A measurement of renewable energy as a share of energy is an indicator of progress in reducing global GHG and local pollution sources, a country’s progress in developing and utilising available resources sustainably, and improving sustainability over the entire energy value chain.

Two measurements are possible. A measurement of renewable energy as a share of TFC can be useful, but it ignores the 6-8% transmission losses that are incurred throughout the transmission and distribution network. A second option is an indicator expressing renewable energy as a share of TPES, but this measurement ignores losses incurred in the combustion of fossil fuels. While both indicators have their advantages, the need to understand primary energy options and implications is important. These measures therefore should be interpreted carefully.

For the UNECE region as a whole, renewable energy from wind, solar, and geothermal accounted for only 1.6% of TPES in 2014. If hydropower, biofuels and waste are included renewable energy accounted for 9% of primary energy supply compared to a global share of 14%42.

Figure 2.12 shows renewable energy as a share of both TFC and TPES for each country in 2014. Countries with high shares of renewable energy, (e.g., Iceland, Norway, Sweden, and Montenegro) “suffer”. There is an obvious transformation efficiency gap for renewable energy. This renewable energy transformation effect is less in Kyrgyzstan and Switzerland because hydroelectric power’s “conversion efficiency” is 100%.

Additionally Indicator: Renewable Energy Generating Capacity Additions

Between 2000 and 2015, the UNECE region witnessed growth in renewable energy43 generating capacity from 434 Gigawatts (GW) to 860 GW. This growth amounted to 38% of all global additions of renewable capacity - consistent with the region’s share of global capacity. Non-hydro additions accounted for 86% of total renewable energy generating capacity, or 372 GW, indicating a progressive shift away from hydro to investment in solar photovoltaic (PV), wind and bioenergy. Hydro’s share remains high with 57% of total installed renewable energy capacity44.

Data Source: IEA World Energy Balances; World Bank et al. (2017).

Source: IRENA (2016).
Over the period 2000-2015, Western and Central Europe led the growth in renewable energy capacity with 23% of capacity additions, followed by North America at 11%. The balance was in Central Asia at 2%, Southeast Europe at 1%, and the Russian Federation at 1% (see figure 2.13). The latter countries represent a small part of the UNECE’s total population and GDP base. Ideally, progress would be measured against a scale of economically realisable renewable energy potential capacity in a country or region.

Comparing the first chart with a more recent period of 2013-2015, the UNECE sub-regions which contributed most to renewable energy installed capacity additions were again Western and Central Europe (15%) and North America (12%) (see figure 2.14). The growth in capacity additions in North America is mainly due to the United States which increased its annual additions from 192 GW in 2013 to 219 GW in 2014, making it the country with the most additions in 2015 in the UNECE region.

The investment figures are roughly double the figure for (excluding large hydro) fell by 23% to USD 241.6 billion, the lowest figure since 2013. In 2015 the figure was USD 258.9 billion, a 5% increase to 2014.45 At the same time, there were record installations of renewable energy capacity in both years, with 134 GW in 2015, and 138.5 GW in 2016. The investment figures are roughly double the figure for investments in fossil fuel based generation.

The decrease in investments is explained in part by falling costs of renewable energy capacity but also by a marked slowdown in financings, mainly in China, Japan and in some emerging markets. The United States saw a reduction by 10% to USD 46.4 billion, while overall Western and Central Europe enjoyed a slight increase, including the United Kingdom with USD 24 billion and Germany USD 13.2 billion, down 1% and 14% respectively.

The 2017 UNECE Renewable Energy Status Report further provides 2015 figures for 17 countries from the Caucasus, Central Asia, Eastern Europe, the Russian Federation, and Southeast Europe.46 The investment figures reported are less optimistic: total investments in the 17 countries declined to USD 400 million in 2015, down from USD 700 million in 2014. Data for 2016 point to a further reduction. Countries of this region only represented 0.2% of total global investments in 2015.

Only three countries, Kazakhstan (USD 100 million), the Russian Federation (USD 200 million) and Ukraine (USD 100 million), saw new investment in renewable energy.

A range of international donors and development banks are active in the renewable energy sector in these countries. They provide technical and financial assistance in form of debt financing and grants for renewable energy projects in the region. However, there is a clear gap between the renewable energy potential and the investment provided in these countries, and further assessment of the barriers and how to overcome these is required.

Additional measures are required to allow these countries to benefit from the forecasted global renewable energy share of almost three quarters of the USD 10.2 trillion (Tn) total investment in new power generating technology until 2040.47

2.2.3. Energy Access

Energy is essential for sustainable development and poverty eradication. According to the UN, in 2015 about 2.8 billion people had no access to modern energy services and over 1.1 billion did not have electricity.48 Historically, high levels of industrialization have provided a high level of physical electricity access in all countries in the UNECE region. The electrification rate in the UNECE region was 99% in 1990, and almost reached 100% in 2010.

In 2014, all countries reported electrification above 99.9%. In rural areas, virtually universal access at the regional level was achieved in 2010. All countries showed a rate of rural electrification above 99.7% in 2014.

North America and Western and Central Europe had universal access by 1990. Caucasus, Central Asia, Eastern Europe, the Russian Federation, and Southeast Europe collectively achieved 100% access between 2007 and 2010. In 2014, 2,500 people across Kyrgyzstan and Tajikistan did not have access to electricity.

Despite 100% physical access to electricity, many countries in the UNECE region are challenged by issues of affordability, quality of access, and service. Many of the infrastructure assets are now old, and substantial renewal and redevelopment is required to improve reliability and quality of supply. For example, it is estimated that more than 60% of the power infrastructure in Kyrgyzstan, Tajikistan and Uzbekistan is older than 60 years (see further information under chapter 2). Power supply in Caucasus and Central Asia suffers where infrastructure maintenance and age reduce supply reliability. In Tajikistan, for example, 70% of the population endure frequent power outages. In 2012, electricity shortages in the winter were estimated at 2,700 GWh, protected to grow to over 6,800 GWh by 2020 in the absence of any offsetting measures.49
Across the UNECE region, five areas were reported with inadequate grid access. These were villages in Kraiina and Eastern Bosnia in Bosnia and Herzegovina; 130 largely seasonal residences in rural settlements in Georgia; 20 settlements in the Batken region in Kyrgyzstan, where traditionally power was supplied from outside Kyrgyzstan; 1,500 remote settlements in Uzbekistan; and Tajikistan where the power grid covers 96% of the country, but 10% of the population in remote mountainous regions do not have access. These examples have supply constraints from remoteness, seasonal occupancy, or as a result of conflicts. In each case, efforts are underway to address access.\textsuperscript{31}

The required upgrade of aged infrastructure provides both a challenge as well as an opportunity for countries. Planning of new energy infrastructure can integrate aspects of sustainability in the context of the SDGs and in particular SDG 7.

Affordability is also an issue in the UNECE and is not only a problem seen in the eastern countries of the region. The European Union has some of the highest end-consumer electricity prices (29.8 Euro-cent per kWh in the second half of 2016)\textsuperscript{56}, and German suppliers reportedly cut electricity to 130,000 households in 2015 due to unpaid electricity invoices.\textsuperscript{53} In Spain, there were more than 7,000 deaths related to energy poverty in 2014, and in Great Britain more than 15,000 in 2015. These figures can be explained mainly by the elderly who do not heat or cool their houses sufficiently.\textsuperscript{34} The World Health Organisation (WHO) estimates that 40% of unnecessary winter mortalities are caused by inadequate living conditions in the European region.\textsuperscript{16}

**Additional Indicator Area: Heat Demand, Affordability of Heating, and Quality of Heat Services**

Many of the region’s countries circle the arctic, and cold continental climates across most of the region create the highest demand for heating services in the world. The region features older, often poorly insulated buildings with old inefficient central or unitary heating systems. Affordability and service quality of heat services are a particular challenge with the lock-in of older fossil based heat infrastructure and poor insulation remaining an important issue in all countries.

Affordability of heating services is a growing challenge. All countries have at least part of their household population in energy poverty, which is generally defined as more than 10% of household income spent on energy. For example, in the Russian Federation 29% of households spend more than 10% of income on energy, while in four other countries more than 40% of households spend over 10% of their income on energy (Albania 46%, Moldova 52%, Serbia 49%, and Tajikistan 60%).\textsuperscript{26}

Security of operation continues to rely on decades-old infrastructure in power systems, district heating networks, and the natural gas network with low efficiency and high losses. Further barriers include a lack of transparency and trust in tariff setting, poor cost recovery and metering, and affordability.

**SDG 7 Indicator: Share of Population with Access to Clean Cooking**

The UNECE region achieved 98% access to clean fuels and technology for cooking in 2014, up from 95% in 2000. With 75.8%, Southeast Europe was the predominant sub-region that did not achieve universal access. Albania had the fastest growth in Southeast Europe and reached 67.1% access, while Bosnia and Herzegovina reported the lowest access, 39.8%, and the slowest growth in 2012–14. Outside of Southeast Europe, only Georgia (55%) in the Caucasus, and Kyrgyzstan (76%) and Tajikistan (72%) in Central Asia, did not achieve access rates above 90%.

In summary, 23.4 million people, 12 million from Southeast Europe, 2 million from Caucasus, 8 million from Central Asia (excluding Turkey), and 1.4 million from Eastern Europe (excluding Israel which has 100% access rates) still relied on traditional fuels for cooking in 2014 in the UNECE region. They mostly lived in remote regions, and relied on locally-gathered firewood. The fuel is typically burnt in a controlled combustion wood stove or a traditional high mass combined space heater and/or cooking oven. Traditional stoves offer users reliable heat from low or no-cost local resources at reasonable efficiencies\textsuperscript{57} and are therefore a preferred option in situations where access to commercial energy sources is impractical or expensive.

### 2.3. Beyond SDG 7: Energy for Sustainable Development

As is noted elsewhere in this report energy is the golden thread that weaves throughout the 2030 Agenda. Addressing the net carbon intensity of the energy system is essential for meeting the climate challenge and herewith SDG 13. Assuring energy access and affordability connect directly to poverty, hunger, health, education, gender equality, water, economic development and employment, infrastructure, inequality, and sustainable cities.

Attaining the objectives of the 2030 Agenda will require full engagement of industry to transform energy. As a consequence, it is essential to monitor progress on energy for sustainable development in ways that reflect the cross-cutting interconnections among the SDGs.

#### 2.3.1. Energy Productivity

Instead of using energy efficiency and energy intensity the concept of energy productivity can be applied. It describes a paradigm shift as it moves from reducing the energy used to optimizing the energy use, e.g. by doing more and using the same or less amount of energy.
Energy productivity expresses the volume of services or products that can be generated per unit of energy. It measures the amount of value added or GDP that can be produced with one unit of energy. This can be done on macro-economic level by dividing GDP by TPES, or on micro-level such as sectors, companies, processes, etc. It is hence the inverse of the concept of energy intensity, an increase in value resembles an improvement in productivity. Nevertheless, it has a series of advantages over using energy intensity as indicator.

The concept of energy productivity is commonly perceived as more positive, since energy intensity is often perceived to carry a negative connotation of using less energy. As most governments are more motivated to improve the country’s social wellbeing, economic productivity and environmental impacts rather than ‘saving energy’, improving the country’s GDP per unit energy productivity is a priority for a number of countries. Intuitively, people tend to adopt concepts more willingly where an improvement leads to an increase in value rather than a decrease.

The concept of energy productivity is further more aligned with energy efficiency, as both measures divide output by input, which leads to an almost synonymous use when applied on sector or process-level.

There are also mathematical advantages. While countries with initially high energy intensity make large gains in absolute and relative terms over time as GDP generally increases faster than energy consumption. On the other side, countries that did not feature positively in terms of energy intensity improvements actually make larger energy productivity improvements in absolute terms.

Similar to energy intensity, energy productivity is not a perfect concept either because it does not reflect differences between countries such as their economic structure, size, or climate.

There is an urgent need to more broadly apply the concept of energy productivity including in business improvement objectives if the global welfare and environmental improvements sought in the UN’s Sustainable Development Goals are to be achieved. Nevertheless, energy efficiency as an indicator does not become obsolete, as it provides an important input to energy productivity by assessing the actual physical improvements to be made to optimize or reduce energy use.

Additional Indicator: Energy Productivity of GDP to Total Primary Energy Supply

Energy productivity can provide useful information when plotted against energy availability measured in TPES per capita. Normalising energy consumption by the number of citizens makes it possible to compare countries despite differences in population. Per capita energy consumption reflects the wealth of a country, the structure of the economy and the efficiency of energy use. However, countries that are structurally similar can differ in terms of energy use per capita because of differences in size or climate. Monitoring shifts in energy productivity and availability over time can give useful insights on energy consumption based on economic structure and climate zones. Similar countries exhibit similar trajectories of productivity and per-capita consumption over time which indicate how rapidly they might progress towards greater productivity and efficiency.

Between 2001 to 2012 most UNECE member States improved their energy productivity despite variances in energy availability (see figures 2.15a-d). Countries with high per capita consumption are prone to reduce energy demand while improving energy productivity. Many European countries show an intense decline in per capita consumption and improvement in productivity over this period.

Most of the Balkan countries are still developing their energy availability. Some countries like Azerbaijan or Tajikistan have made major shifts in productivity but still have low levels of energy intensity or low energy availability. In contrast, other countries like Kazakhstan or Turkmenistan have massively increased per-capita consumption but achieved moderate improvement in productivity.

**FIGURE 2.15A: Productivity Trends 2001-2012 in North America and North-West Europe.**

**FIGURE 2.15B: Productivity Trends 2001-2012 in Western and Central Europe.**
Chapter II: Tracking Sustainable Energy Progress in UNECE

2.3.2 Fossil Fuels

Given that UNECE region’s share of fossil fuels in TPES is 80%, and will likely remain above 50% over the time period, the transition to a clean, affordable and low-carbon energy system will require solutions for the use of fossil fuels. To achieve net zero emissions by the second half of this century, the region’s historical dependency on fossil fuels needs to be reduced or there must be a strong focus on carbon capture and storage (CCS).

To track progress towards this objective, the share of fossil fuels within the energy system must be one indicator to measure progress towards a low-carbon future. Other indicators could include the efficiency of fossil fuel based power generation capacities and methane (CH4) emissions along the energy value chain. Some data are provided below.

Additional Indicator: Share of Fossil Fuels in Total Primary Energy Supply

In 2014, 80% of UNECE’s TPES came from fossil fuels, compared to the global share of 81%. The balance was made up of 10% nuclear and 9% renewable sources of energy including hydro, biofuels and waste, as well as geothermal, solar and wind. Figure 2.16 gives an overview of the share of fossil fuels in each sub-region.

The figures vary across the UNECE sub-regions from 71% in Western and Central Europe to 94% in Central Asia. For more analysis on the role of fossil fuels in the UNECE region, please see Issue 1 in Chapter 5.3.

2.3.3 Climate Commitments

SDGs 7 and 13 are linked through the Paris Climate Agreement that aims to limit global warming to well below 2°C. Meeting them both requires clear understanding of the climate-related impacts of energy and the development-related opportunities of energy. Meeting the climate change challenge necessarily involves fundamental transformation in how energy is produced, transformed, transmitted, and used.

According to the Intergovernmental Panel on Climate Change’s (IPCC) Fifth Assessment report, mitigation scenarios aiming to limit global temperature increases below 2°C over the 21st century include substantial cuts in anthropogenic GHG emissions by mid-century. These cuts will have to be achieved through both large-scale changes in energy systems and potentially land use. The mitigation scenarios are characterized by more rapid improvements in energy efficiency and a tripling to nearly a quadrupling of the share of zero- and low carbon energy supply from renewable energy, nuclear energy and fossil energy with CCS, or bioenergy with CCS (BECCS) by the year 2050.60

The IPCC report confirms that energy plays a crucial role in combating climate change. The CO2 emissions from fossil fuel combustion and industrial processes contributed about 78% of the total GHG emission increase from 1970 to 2010.61 According to the IEA, 80% of global CO2 emissions come from the energy sector, while it contributes a third to global GHG emissions.62 The two most relevant GHGs are CO2, mainly from the combustion of fossil fuels, and methane along the energy value chains. Three indicators are suggested to track progress towards a less-carbon intensive energy sector: GHG intensity of TPES, GHG intensity of TFC, and per capita GHG intensity of energy. The UNECE region also is falling short on these relevant indicators.
Additional Indicator: CO₂ Emissions from Fuel Combustion

Over the 1990-2010 period, total CO₂ emissions from fossil fuel combustion increased by about 45% globally. In 2010, CO₂ contributed 76% of global GHG emissions (one third from the energy sector), CH₄ (methane) about 16%, N₂O about 6% and the combined fluorinated gases (F-gases) about 2%. The UNECE region contributed 36% of global CO₂ emissions from the combustion of fossil fuels in 2014 (see figure 2.17), which is about 11 GtCO₂ out of the total global 32 GtCO₂ emitted. While globally there was a small increase of emissions less than 1% compared to 2013, CO₂ emissions in the UNECE region saw a reduction in 2014 compared to the previous year. North America has the largest share at 18%, Western and Central Europe at 10%, the Russian Federation 5%, Central Asia 2%, Eastern Europe and Southeast Europe 1% each, compared to China with 28%.

In light of commitments made under the Paris climate agreement, UNECE countries need to address GHG emissions from the energy sector. Country sizes vary considerably, and while emissions must be tackled at an absolute emission level, normalizing emissions by factors such as population, geographical area or economic activity offers useful insights into the scope and capacity for change.

On a per capita basis there is considerable range in the carbon intensity of fossil fuel energy (in tCO₂/capita) in UNECE sub-regions. With 9.1 tCO₂/capita in 2014, the UNECE average is two times higher than the global average of 4.5 tCO₂/capita. Figure 2.17 shows the trend for CO₂ emission per capita for the UNECE sub-regions.

Since 1990, most sub-regions have converged towards the world average per capita emissions, especially the former Soviet Union countries, Caucasus, Central Asia, Eastern Europe, and the Russian Federation. Central Asia has tracked the world average closely, while Western Europe and North America showed later progress as their post-millennial policies on energy efficiency, renewable energy and climate took effect. Figure 2.18 shows that UNECE countries have high per capita fuel combustion CO₂ emissions to address in order to achieve sustainable energy.
Chapter II: Tracking Sustainable Energy Progress in UNECE

In addition to IEA data, the United States Energy Information Administration (EIA) publishes data for total CO₂ emissions from the consumption of energy. Figure 2.19 provides an overview of emissions within UNECE with the darkest shades representing the highest emitters.

Additional Indicator: Carbon Intensity of Primary Energy and Final Energy Consumption

The carbon intensity of primary energy is calculated by dividing all net CO₂ emissions from fuel combustion by TPES (tCO₂/TJ). The carbon intensity of final energy consumption is calculated by dividing all net CO₂ emissions from fuel combustion by TFC (tCO₂/TJ).

According to IEA data, the global carbon intensity of primary energy in 2014 was 56.6 tCO₂/TJ, averaged over all energy sources including fossil fuels, nuclear and renewable energy. Figure 2.20 shows the development of this indicator for the different UNECE sub-regions from 1990 to 2014.

The carbon intensity of primary energy sources differs significantly across the regions. Central Asia and Southeast Europe’s trend is upwards until 2012.

Western and Central Europe has witnessed a continued decline of carbon intensity. In 2014 the sub-region reported 47 tCO₂/TJ, well below the global carbon intensity of 56 tCO₂/TJ.

Figure 2.21 gives a detailed overview of the 2014 carbon intensities at sub-regional level. The highest national carbon intensity figures for TPES in the region are Malta, Poland, Estonia and Kazakhstan with 72, 71, 70, and 70 tCO₂/TJ, respectively.

Data Source: IEA World Energy Balances.
Chapter II: Tracking Sustainable Energy Progress in UNECE

2014 figures for TFC are given in Figure 2.22 and the carbon intensity trends for 1990-2014 are shown in Figure 2.23. Only the sub-regions of Caucasus, North America, and Western and Central Europe are below the global figure of 90 tCO₂/TJ. The highest national carbon intensity for final energy are Estonia and Kazakhstan with 150 and 149 CO₂/TJ, respectively.

**FIGURE 2.21: CO₂ Emissions from Fuel Combustion per TPES for UNECE Sub-Regions (2014, in tCO₂/TJ).**

**FIGURE 2.22: CO₂ Emissions from Fuel Combustion per TFC for UNECE Sub-Regions (2014, in tCO₂/TJ).**

**FIGURE 2.23: CO₂ Emissions from Fuel Combustion per TFC for UNECE Sub-Regions (1990-2014, in tCO₂/TJ).**

Data Source: IEA World Energy Balances.
Additional Indicator: Greenhouse Gas Intensity of the Energy Sector

In 2010, CO₂ emissions from the energy sector were 76% of global GHG emissions. Other GHGs such as CH₄, N₂O, and the combined F-gases accounted for about 16%, 6% and 2% of global emissions, respectively. In order to calculate the GHG intensity of the energy sector, additional data sources are required. Energy-related emissions are communicated as part of UNFCCC processes through the official national emission inventories. Figure 2.24 shows data for GHG emissions per TPES in tCO₂/TJ for those countries for which data was available from the UNFCCC. As the reporting dates differ significantly, a time span of 2012-2014 is presented, indicating results for countries from different years.

**FIGURE 2.24: Energy-Sector Greenhouse Gas Intensity in TPES in UNECE countries (2012-2014, in tCO₂/TJ).**

Data source: UNFCCC (2017a); IEA World Energy Balances.

Figure 2.25 shows the GHG emissions per TFC. Countries with a large share of fossil fuels in their energy mix have higher intensities such as in the case of the Russian Federation and Poland, compared to countries with a large share of low-carbon energy solutions such as nuclear and renewable energies, for example, in the case of France and Norway. Compared to the carbon intensity of TPES, the carbon intensity of TFC reflects conversion efficiencies as well as the GHG emissions and energy content from energy production. For comparison, total GHG emissions by country (not only the energy sector) for 2012 is shown below in figure 2.26. According to this data source, the UNECE region contributed 32% or 17 GtCO₂eq of total global GHG emissions in 2012, compared to the global total of 54 GtCO₂eq.

**FIGURE 2.25: Greenhouse Gas Intensity in TFC in UNECE Countries (2012-2014, in tCO₂/TJ).**

Data source: European Commission Joint Research Center (2014).
III. Sustainable Energy in UNECE: Selected Issues and Country Case Studies

This part of the report explores country experiences that underpin the data reported in Section 2. As outlined in Chapter 1, the aim is to highlight systemic challenges and recognise that all elements in an energy system are connected, similar to the interdependencies of the SDGs: human needs drive demand for services, which in turn drives demand for energy technology, and in turn drives supply investments and resource demand.

3.1. Overview to Issues Considered in this Report

The energy system explained in Figure 1.2 in Chapter 1 above forms the basis of a system logic that influences the policy drivers to improve the sustainability of the energy system.

An overview of the issues and case studies is presented in Table 3.1. The following sub-chapters look at the issues, potentials and prospects for each element of the energy system.

3.2. Improving Required Energy Services

The need to improve consumer service is a significant challenge. Despite the high levels of access reported by the GTF indicators, for many consumers connection to a utility network bears little relation to the services actually received through the connection.

As outlined in chapter 2, much of the infrastructure in the UNECE region derives from mid-20th century, it is old, less than reliable, and faces important quality of supply challenges. Discrete pockets of remote settlements with limited access to grid power remain.

3.2.1. Selected Issues and Country Responses

The level of service quality achieved by households and businesses is a combination of three aspects of consumer end use.

Access to energy

At a naïve level, access is indicated by connections to electricity, gas or heat networks. The capacity, consistency and quality/reliability of supply can vary considerably in established networks even with 100% connections for households and businesses.

Affordability of energy

In all countries lower socio-economic groups struggle to afford to purchase energy they need. Typically, less well-off households and businesses make trade-offs, compromising quality and quantity of food, clothing or health care to maximize utility from a limited service capability while maintaining basic levels of comfort for health.

Issue 1: Heat services – A Critical Service with Substantial Quality and Sustainability Challenges

While consumers need diverse energy resources, heat services stand out in the UNECE region as a critical resource due to the prevalence of extreme cold.

The region’s countries circle the arctic, and cold continental climates over most of the region create the highest demand for heat services in the world in almost all UNECE countries except those bordering the Mediterranean and the southern states of the USA (see figure 3.1).

While consumers and policy makers can influence a number of variables, weather and climate are outside of their control. Cold climates oblige more energy use to ensure human health and wellbeing. The extent of heating demand can be described by Heating Degree Days – the cumulative number of degrees over a year that daily average temperatures are below 18°C, a recognized temperature below which buildings need to be heated. UNECE region countries face a higher demand for heat services than any other region.

The historical high dependence on fossil fuels for centralized heat services and lack of investment capital creates a locked-in dependence on fossil fuels. This is often associated with

</table>
poor efficiencies and a perception of heating security based on indigenous (typically fossil) energy resources. There is enormous scope for improvement in the adequacy of heat services in the region, including both their efficiency and their affordability.

Heating services in buildings and industry represent over 40% of final energy consumption in the UNECE region (see case study 1). By contrast, in Western Europe, the Russian Federation and United States, energy for cooking is less than 4% of total heat services. Generally cooking is undertaken with commercial cooking fuels (gas and electricity). Exceptions occur in remote areas where controlled combustion wood stoves provide heating and cooking services. 13 million people in 17 countries still rely on solid fuels for cooking. Bosnia and Herzegovina and Georgia stand out with 42% and 54% access, respectively, to non-solid fuels for cooking.72

Four key aspects of heat service access and service quality warrant attention.

I. Legacy Systems: Many buildings and energy systems in Eastern Europe, Central Asia, date to post-war reconstruction. Upgrading or replacing infrastructure to improve service quality across the eastern sub-regions of the region is a much larger task than provision of access to the remaining areas with poor access. Both are priorities and require an underlying policy base that ensures investment is allocated efficiently to achieve service and access quality improvements and a simultaneous economic transition to distribute renewable energy. Ensuring affordability and access to quality of service merit further exploration.

II. Adequacy of Service: Adequacy of heat service, efficiency and affordability remain challenges in most countries. A high level of energy access, measured as connections to final energy
systems, does not measure service quality. Those countries that recognise energy poverty (the inability of households to maintain safe indoor temperatures without undue burden on their income) face complex barriers of built–in inefficiencies, capacity to pay and access to modern efficient technology.

**III. Fossil Dependency:** While the generators and engines in power generation and transport fleets require liquid or gaseous fossil fuels, heat services are still highly dependent on fossil fuels. The institutional and technological infrastructure was designed to use historically available fossil fuels. There is a locked-in dependence on fossil fuels, Primary transformation processes in power generation, and energy provision also face locked-in dependence on fossil fuels with often poor efficiencies. The transition is neither obvious nor easy, however, great potential exists when infrastructure modernisation is undertaken in connection with the development of solid national energy strategies.

**IV. Energy Security:** Most countries of the region focus on energy security based on indigenous (typically fossil) energy resources. While many UNECE countries are major exporters of energy resources to global markets, strong regional and cultural behaviours lock in an on-going reliance on indigenous resources. If growing energy demand is to be met, in the near that will likely be covered by existing fossil resources as renewable energy sources and infrastructure are not yet adequately developed.

An integrated approach to energy efficiency in buildings could pave the way for other sectors. Addressing heating needs and economically optimising investments in both end-use energy efficiency and renewable energy could provide the enabler for other approaches to follow suit. Supportive policy frameworks need a long term perspective: integrating building owners, the building sector and financiers in substantial retrofits. Reticulated gas and district heating systems tend to exist in cities. Smaller settlements and rural areas are much more likely to depend on solid fuels for heat services and cooking.

**A chance to re-think the sustainability of heat?**

Lower costs for distributed renewable energy and better insulated homes and high costs for updating ageing central district heating systems is enabling a shift from economically unsustainable subsidised heat supply systems. Many district heating systems operate within a municipal mandate that required connection, were built without heat metering, and have struggled under central control economics to update as societal demands evolved. See more information in case study 2.

---

### Case Study 2: District Heating.

Globally, 15.8 EJ were used in 2010 (2.6 % of global TPES) to produce nearly 14.3 EJ of district heat for sale by Combined Heat and Power (CHP) (44%) and heat-only boilers (56 %). After a long decline in the 1990s, district heat returned to a growing trajectory in the last decade, rising by about 21 % above the year-2000 level (IEA, 2012a). This market is dominated by the Russian Federation with a 42% share in the global heat generation, followed by Ukraine, United States, Germany, Kazakhstan, and Poland. Natural gas dominates in the fuel balance of heat generation (46%), followed by coal (40%), oil (5%), biofuels and waste (5%), geothermal and other renewables (2.4%), and a small contribution from nuclear.

Development of intelligent district heating and cooling networks in combination with (seasonal) heat storage allows for more flexibility and diversity (combination of wind and CHP production in Denmark) and facilitates additional opportunities for low-carbon technology (CHP, waste heat use, heat pumps, and solar heating and cooling). In addition, excess renewable electricity can be converted into heat to replace what otherwise would have been produced by fossil fuels. Statistically reported average global efficiency of heat generation by heat-only boilers is 83%, while it is possible to improve it to 90–95% depending on fuel used. About 6.9 % of globally generated heat for sale is lost in heating networks. In some Russian and Ukrainian municipal heating systems, such losses amount to 20–25 % as a result of excessive centralization of many district heating systems and of worn and poorly maintained heat supply systems.

The promotion of district heating and cooling system should also account for future technology developments that impact the district heating sector (building heat demand reduction, high-efficiency single-housing boilers, heat-pump technology, cogeneration reciprocating engines, or fuel cells, etc.), which may allow switching to more efficient decentralized systems. District heating and cooling systems could be more energy and economically efficient when heat or cold load density is high through the development of tri-generation, the utilization of waste heat by communities or industrial sites, if heat (cooling) and power loads show similar patterns, and if heat-loss control systems are well-designed and managed.

Distributed renewable energy is now competing directly with fossil fuel options and taking market share in new plant construction. When used in conjunction with modern low-energy construction techniques, distributed renewable energy is also starting to challenge district heating systems, particularly older smaller systems with often marginal operational economics.

The question is if distributed renewable energy options offer a lower life-cycle cost to consumers and governments than ongoing system costs of existing district heating such as replacement costs for the less economic parts of a district heating system.

Case study 3 provides information on the European Union’s policy actions for heating.
Chapter III: Sustainable Energy in UNECE: Selected Issues and Country Case Studies

### Issue 2: Quality of Supply Challenges Remain, Despite Universal Electricity Access

Electrification rates (the ratio of electricity connections to number of households) across the entire UNECE region have been reported at 100% since 2012. Only Armenia, Azerbaijan, Bosnia and Herzegovina, Kazakhstan, FYR of Macedonia, Moldova and Ukraine had electrification access levels below 95% in 1990 and these have since achieved 100% electricity access. Countries in the UNECE region meet the objective for electricity access in the sense of connections to networks, but there are still aspects of this objective that warrant policy attention. There are still ‘pockets’ of remote settlements where access to electricity remains a challenge:

- Small villages in Bosnia and Herzegovina face abnormally high costs to reinstate electricity distribution systems damaged during the 1990s conflict. The Government, supported by the United Nations Development Programme (UNDP), is developing distributed renewable power solution projects for these communities.
- A 2012-2016 Georgia rural electrification programme, supported by the United States Agency for International Development (US AID), as connected 29 off-grid villages.
- The Kyrgyzstan Government and Islamic Development Bank are redeveloping supply to 20 settlements in the Balkan region, including supply from Tajikistan.
- In Uzbekistan 1500 settlements (predominantly in the Republic of Karakalpakstan) have no commercial electricity supply. Solutions underway include residential scale solar systems and government promoted mini hydro.
- In Tajikistan, the electricity grid covers 96% of the country, but remote settlements still have no grid connection. A more significant issue is that 70% of the population face outages from reduced winter hydro inflow.

### Case Study 3: European Union Policy Actions for Heating

Article 14 of the European Union’s Energy Efficiency Directive 2012/27/EU issues comprehensive guidance on: identifying and implementing adequate measures for efficient district heating and cooling infrastructure, the development of high-efficiency cogeneration, the use of heating and cooling from waste heat and renewable energy sources, where benefits exceed the costs. Procedures for operators of electricity generation installations, industrial installations and district heating and cooling installations to ensure that they carry out an installation-level cost-benefit analysis on high-efficiency cogeneration and/or the utilization of waste heat and/or connection to a district heating and cooling network when they plan to build or refurbish capacities above 20 MW thermal input or when they plan a new district heating and cooling network.

### Issue 3: Energy Affordability

The UNECE region is particularly challenging in heat services. For example in the Russian Federation 29% of households spend more than 10% of income on energy, in 4 UNECE countries more than 40% of households spend over 10% of their income on energy (Albania 46%, Moldova 52%, Serbia 49%, and Tajikistan 60%).

In reality each of these issues combine together, those that struggle to purchase energy, also struggle to afford and get access to the efficient appliances that will lower their dependence on constrained access to energy, and lower their energy costs.

A service quality affordability problem.

Six UNECE countries have aggregate energy intensities below the 0.06 EJ/capita (or 1.5mtoe/capita): Bosnia and Herzegovina, Tajikistan, Turkmenistan, Uzbekistan, Kyrgyzstan, Montenegro, and Georgia. While these countries can improve their energy efficiency and expand the current crop of...
economic renewable energy, their prospects for productivity and development would improve by improving the quality of their energy access. These countries warrant attention from access initiatives.

There is no comprehensive study on energy poverty across the UNECE, but insights across the European Union and other countries show both universality to energy poverty and huge variety in experiences. Any Country will have a share of its population struggling to pay energy bills or heat their homes. Examples include:

- The Building Performance Institute Europe estimates 54 million people cannot afford to heat their homes in winter, and 50 and 125 million persons live in energy poverty in the European Union.90

- Energy poverty is more prevalent in Central and Eastern Europe, where it rose dramatically with the end of state subsidies for energy and increased poverty in general in the 1990s. More than 40% of people in Bulgaria were not able to keep their homes warm in 2014, and 32.9% were behind with their bills. The impacts can be disproportionate. According to the European Fuel Poverty and Energy Efficiency project, groups most at risk are retired and unemployed people, the working poor, those on welfare, elderly and disabled people and single parents.91

- The award winning Cold@home website explores the impact on the lives of individuals struggling with energy poverty in documentary form.92

- A study from the United Kingdom showed that while 87% of low-income households were able to pay with their bills, typically they cut back on non-essentials, food and heating. 63% of those who saved on heating were also saving on food, and 59% of those who saved on food were economising on heating93 (see also case study 5).

- A study on Vienna identified that the ways of handling this problematic situation vary greatly and that people follow different strategies when it comes to inventing solutions for coping with the restrictions that high energy bills impose on the household.94

The impact on humans is real has consequences in terms of unnecessary health and welfare costs. The consequences of energy poverty are numerous: an excess number of winter deaths, respiratory problems, increased hospitalisations, greater incidences of mental diseases, as well as negative effects on social life, relationships and education of children.

**Energy efficiency is central to addressing energy poverty**

A number of options exist for alleviating energy poverty: social welfare payments, progressive tariffs for energy, policies limiting disconnections, information and consumer protection policies. These address the symptoms of poor service, but some are more socially and economically efficient than others. Some measures may produce progressive outcomes, others may create distortions – subsidising one attribute of welfare at the expense of another. Only improving energy efficiency goes to the heart of the problem addressing the underlying failure of efficient service delivery. A 2010 European Commission paper considers energy efficiency one of the most effective long term measures for lifting people out of energy poverty.

### 3.2.2 Opportunities and Prospects

Increasingly, consumers are finding ways to cooperate and address energy service problems and household sustainability themselves. Many cities have community level household sustainability and home weatherization co-operatives that make measurable improvements to vulnerable households despite limited resources. Community-led action can often tackle challenges more effectively than government alone, developing solutions to meet local needs. Putting communities in control of the energy they use can improve energy security, tackle climate change, help people save money on their energy bills, improve resilience of communities, and deliver social and economic benefits. However, committed action by the central government is still needed to drive improvements in energy service and address energy poverty.95

---

**Case Study 5: Community-led Sustainable Energy Programmes in the United Kingdom.**

The United Kingdom’s government’s Community Energy Strategy empowers local government to act on identified energy access and poverty challenges and develop local sustainable energy resources by: Generating electricity or heat; Reducing energy use through energy efficiency and behaviour change; Managing energy by balancing supply and demand; Purchasing energy in collective purchasing processes or switching suppliers to reduce costs (21,000 households switched energy suppliers through the Cheaper Energy Together scheme, leading to an average costs saving of £131).

At least 5,000 community energy groups have been active across the United Kingdom since 2008. Community energy projects are currently focused on renewable electricity generation, with the most prevalent technology being solar PV and onshore wind. At least 60MW of community-owned renewable electricity generation capacity is currently in operation. While this remains a small fraction of installed renewable electricity generation capacity, it is located close to communities and there is significant potential for growth. Energy regulators, local authorities, power project developers are required to work with communities. The Government is establishing a dedicated Community Energy Unit to act as the Department’s policy lead on community energy and to take forward implementation of the strategy.96

Prominent health impacts associated with energy efficiency improvements include reduced respiratory disease symptoms and lower rates of excess winter mortality (EWM) in cold climates. Fewer deaths from dehydration are reported in heat extremes. Aside from potential energy demand reductions, improving energy efficiency in buildings creates conditions that support improved health and wellbeing for occupants. Positive health outcomes are consistently strongest among vulnerable groups, including children, the elderly and those with pre-existing illnesses.

Recent evidence shows that chronic thermal discomfort and fuel poverty have negative mental health impacts; energy efficiency improvements can improve mental wellbeing.

Health improvements at the individual level generate indirect social impacts and relieve pressure on public health budgets. Modelling of a high energy efficiency scenario showed that reduced indoor air pollution could save the European public health budget USD 99 billion per year in 2020.

Overlaying proven metrics and assessment methods from epidemiological disciplines with financial metrics can generate market values for identified health benefits, enabling these outcomes to be built into robust policy assessment frameworks.

When quantified health and well-being impacts are included in assessments of energy efficiency retrofit programmes, the benefit-cost ratio can be as high as 4:1, with health benefits representing up to 75% of overall benefits.

The body of evidence linking improved health and wellbeing to energy efficiency measures has prompted several governments to make addressing fuel poverty a central element of energy policy, often optimising investments by targeting vulnerable groups.97

The scale of energy poverty is significant in a number of UNECE countries and warrants closer evaluation. Until the scale and impact on human welfare from the three aspects of energy service are quantified, energy poverty will remain a poorly recognized and diffuse policy challenge.

Upgrading or replacing infrastructure to improve access across the Eastern sub-regions of UNECE is a larger task than provision of access to the remaining areas with poor access. Both are priorities and both require an underlying analytical and policy base that ensures investment is efficiently allocated to achieve service and access quality improvements, releases multiple social benefits and a transition to renewables.

The overall pace of adoption of clean fuels and technology for cooking remains slow. A continuation of current trends would mean that only six additional countries would achieve universal access by 203098 (Azerbaijan, Latvia and Ukraine by 2020, and Estonia, Croatia and Moldova by 2030). Albania, Bulgaria, Kazakhstan, Romania and Uzbekistan are expected to reach 100% access by 2040, and the Kyrgyzstan by 2050. The remaining six countries are not expected to reach universal access before 2050. Again this is an area that deserves evaluation in order to better understand the barriers and options for progress.

Consumer norms are not static. Changes in technology stimulate change in energy culture: new heating devices and new insulating technology shift perceptions and accepted norms about warmth and comfort, leading to new material cultures (thermal curtains, better insulation, new heating systems, LED lighting, better refrigerators) and practices (closing curtains, heating bedrooms, tracking electricity consumption).

3.3 End-Use Energy Efficiency

Energy efficiency improvements have a clear impact on consumers: reducing energy costs, boosting business performance and delivering more services for household consumers. Energy efficiency is represented by better cooling and heating systems, more efficient appliances, and advanced vehicles. Investing in energy efficiency is crucial to addressing future energy demand growth and mitigating climate change.

It improves productivity and leads to reductions of local pollutants and GHG emissions.

Energy efficiency improvements deliver reductions in per capita energy demand and increased utility to consumers (better light, warmer homes, higher productivity, public budget reductions, and supply side cost reductions). This important aspect is often undervalued in policy making and investment decisions, but delivers a range of micro and macroeconomic outcomes.99 The multiple benefits of energy efficiency can be worth much greater than the value of avoided energy demand, and represent the added value resulting from increased energy productivity.

A key issue for policy makers is that the full range of outcomes need to be understood when developing investment options and designing climate mitigation policies.100 For example, the term energy rebound effects describes the phenomenon that improvements in energy efficiency can lead to greater use of energy services provided, hereby offsetting the initial energy saving potential of energy efficiency measures.101 Rebound effects may reduce the contribution of energy efficiency improvements to climate change mitigation. Such effects could alter the relative priority of different CO\textsubscript{2} abatement policies. Efficiency rebounds can reach 60%, with rebound in developing countries likely much higher than in rich countries.102

3.3.1 Selected Issues and Country Responses

Economic growth and static energy demand in the UNECE region reduced average energy intensity from 8.0 MJ/USD in
1990 to 5.1 MJ/USD in 2014. Energy intensity is however not the same as energy efficiency. Energy efficiency describes the concept of using less energy to provide the same service. Energy intensity describes the ratio between TPES and GDP of a country. Energy efficiency is hence a contributing factor in energy intensity, but the concept contains many other elements, including the structure of the economy (e.g. large energy-consuming industries), the country size (transport sector demand), the climate (heating / cooling demand), and the exchange rate. Changes in activity levels (number of homes, population, GDP etc.) and structure (size of homes, industry activity mix, etc.), and fuel mix changes, confound the clear measurement of energy efficiency and need to be isolated using decomposition techniques. So while energy intensity is used as a prime indicator for energy efficiency, it is only a proxy and is subject to significant extraneous drivers.

Reduction in energy intensity has led to significant reductions in energy consumption. UNECE region energy intensity improvements since 1991 have reduced energy demand in 2014 by 131EJ below what would have been required if energy intensity had been held at 1990 levels. There is much scope to continue this trend.

Improvements in energy intensity are happening, but not fast enough. The average compound annual growth rate (CAGR) of energy intensity in the UNECE region was -1.9 % for the period 1990-2014, while the objective is to attain a -2.6 % rate for the period 2010-2030. Although the UNECE region collectively has reduced energy intensity in industrial, transport and service sectors, the rate of improvement has regressed since 1990 and is uneven as some countries make slower progress than others, despite the attractive economics of energy efficiency.

Drivers for Improving Energy Efficiency

Key drivers for energy efficiency improvements include cost-reflective prices and consistent, enduring energy efficiency policies. Both drivers are required to drive enduring energy intensity improvements. They influence end-use efficiency and utility efficiency investments notably in North America. Long running energy efficiency policies like minimum energy performance standards (MEPS), corporate average fleet efficiency standards (CAFE), and building codes work in a context of competition to improve productivity, displace inefficient production and drive energy efficiency innovations such as electric vehicles and advanced ICT systems.

Achieving absolute energy efficiency improvements requires prices and policies that redefine the energy system as an interconnected cost-reflective system, rather than a supply dominated system. An ‘end-use energy efficiency first’ demand side led approach also minimizes demand on upstream systems and fossil fuel transition costs, enhances the contribution of renewables investments, and optimizes socio-economic and environmental outcomes.

Issue 1: Pollution and Energy Waste from Low Efficiency Heating Systems and Poor Insulation

With a high need for heating services and a high dependence on fossil fuels, both local and global pollution are a significant issue in some countries where locked in reliance on coal, poor heating system efficiency and poor insulation compound to create abnormal air quality problems (see case study 6 below). The choice is stark – either provide heating for human safety and comfort with dangerous levels of air pollution, or suffer inadequate heating.

Effecting change requires a coordinated effort on insulation, heater efficiency and emission controls and access to alternative non-polluting fuels. Industry and transport offer significant opportunities for improved well-being, economic performance, and air quality. This requires central government action on improved heating appliances, improve insulation in buildings, improved industrial energy efficiency, and cleaner and more efficient transport options. Case study below provides more information on the harm from poor fossil fuel based heating.

Case Study 6: Local and Global Harm from Poor Fossil Heating and Building Inefficiencies in Poland.

The clean fuels and fuel wood heaters that dominate heating services across most of the UNECE region can provide heat with relatively low levels of pollution. However, where heating services rely on coal, local as well as global emissions are a significant challenge. It is difficult to burn a complex fuel like coal at low particulate emission levels. Some 400 cities in Europe exceed the daily norms for PM10 levels (50mg/m3 24hr concentration), with 6 of the 10 most polluted cities in Poland and the remainder in Bulgaria.

In Poland, 70% of single-family homes are heated with coal, with 60% with manually controlled heaters. Despite monitoring and fines by the European Union for exceeding set standards, the problem persists. There are no standards for coal heaters in Europe. 140,000 new coal heaters are installed every year, adding to a stock of 3 million uncontrolled coal burners. The problem is exacerbated by the 3.6 million homes in Poland (70%) that have little or no insulation and only 1.37 million homes with average or better insulation. Market research indicates that 51% of households would be prepared to take up subsidies and loans for energy efficiency improvements.104

Issue 2: A Lack of Energy Efficiency Building Codes and Slow Retrofittting of Buildings

Between 1990 and 2014, residential energy intensity across the UNECE region increased from 25 to 26 MJ/capita. Residential energy intensity increased from 36 to 37 MJ/capita in North America. In Southeast Europe intensity increased from 15 to...
that supporting labelling, performance tests and incentives have in countries where policies have matured. Furthermore, the existence of regulation does not imply any degree of compliance with it, and few countries have effective compliance management.

Supply chains for more energy-efficient buildings and the compliance infrastructure are often underdeveloped. Although energy efficiency standards for buildings were introduced in many countries in the 1990s, compliance enforcement is underdeveloped, or may be effective only in larger apartments or commercial buildings. In many countries, poor management of energy efficiency features at the architectural design phase and inconsistent implementation during construction means regulations may be largely ineffective by themselves.

Capacity development is crucial to develop the abilities for compliance management. Knowledge on how to conduct compliances checks as well as resources to implement it are required at the regulator's level.

Source: IEA (2012a).

Building codes tend to apply to new buildings and the existing under-insulated building stock is not addressed. Finland’s Decree (4/13) on improving the energy performance of buildings undergoing renovation or alteration is one of the few regulatory codes that address existing buildings by providing minimum standards for improving energy performance of buildings in renovations and alterations. Within federations, national building codes provide a framework, typically with individual states undertaking state codes consistent with the national code, but responding to state level climatic and other drivers.

The UNECE publication “Good practices for energy-efficient housing in the UNECE region” outlines a range of policy and identifies measures to improve occupant comfort and health and reduce energy demands. An UNECE-led initiative on Framework Guidelines for Energy Efficiency Standards in Buildings seeks to disseminate transformational, principles-based performance guidance for building energy standards. The effectiveness of regulatory measures is improved by complementary measures. Some UNECE member countries implement non-regulatory measures that fall into three policy classes:

- Controlled consumer information: energy performance certificates, home energy rating schemes, voluntary labelling (e.g., ENERGY STAR ratings for the energy efficiency of new homes),
- Design tools; Passive House and Zero Energy requirements as voluntary codes,
Fiscal and financial incentives; tax breaks for energy efficient homes, tax deductions for energy efficiency equipment, funds or grants for energy efficiency retrofit programmes.

Other areas that deserve further review include compliance monitoring and evaluation, carbon certification and targets for buildings (like the United Kingdom’s Carbon Energy Targets CERT), and benchmarking different financial assistance and grant schemes to identify best practices.

**Issue 3: Improving Appliance and Equipment End-Use Efficiency**

With current information systems, an evaluation of appliance and equipment efficiency is not possible as energy consumption and costs are not accounted separately from building costs.

**Case Study 7: Appliances and Equipment Efficiency: The European Union’s Eco-Design Directive 2009/125/EC.**

The European Union’s Eco-design Directive Ecodesign Directive 2009/125/EC sets MEPS for 23 classes of energy using products. Ecodesign legislation, which sets minimum energy efficiency requirements, applies to many everyday products sold in the European Union, such as dishwashers, fridges and heaters. Some types of product must also display energy labels which show how efficient they are. Under the Eco-design Directive, four of the most energy intensive industrial products (electric motors, circulator pumps, fans and water pumps) are regulated to minimize energy costs and environmental impacts over their respective life cycles and will lead to energy demand reductions across the EU of 195 TWh by 2020. The policy has been accompanied by significant technology development and has initiated European Union and global standardization processes.

By 2020, use of energy efficiency labels and Ecodesign requirements is projected to lead to energy savings of around 165 Mtoe (million tonnes of oil equivalent) in the European Union, roughly equivalent to the annual primary energy consumption of Italy. In relative terms, this represents a potential energy saving of approximately 9% of the European Union’s total energy consumption and a potential 7% reduction in carbon emissions. In 2030, this saving is projected to grow to 15% of the European Union’s total energy consumption and 11% of its total carbon emissions.
Minimum Energy Performance Standards and Labelling

One-off improvements of more than 30% have been observed when new energy efficiency standards and labelling programmes are introduced to a market where few energy efficiency schemes existed previously. These substantial efficiency improvements for individual appliances and equipment have translated to national energy savings and reductions in CO₂ emissions. The most mature national energy efficiency standards and labelling programmes cover a broad range of products and are estimated to save between 10% and 25% of national or relevant sectoral energy consumption. In all of the energy efficiency standards and labelling programmes reviewed by the IEA's Energy Efficient End-Use Equipment Programme (4E Programme), the national benefits outweighed the additional costs by a ratio of at least 3 to 1. Case study 8 provides more detailed information from Turkey.

Energy efficiency standards and labelling programmes deliver energy and CO₂ reductions while also reducing total costs. Appliances and equipment covered by energy efficiency standards and labelling programmes have not only dramatically improved in efficiency over the past 20 years, but are also cheaper to purchase. While energy efficiency standards and labelling programmes may have caused small changes in prices close to the implementation of new energy efficiency measures, they appear to have had little long-term impact on appliance price trends.

### Case Study 8: Appliance Energy Efficiency Market Transformation Process in Turkey.

The most important component and starting point for a successful market transformation is the improvement of regulatory framework in agreement with local manufacturers. In the case of Turkey, Customs Union and the presence of worldwide reputable manufacturers in Turkey became an important driving force for an accelerated market transformation. These facts led Turkey to adopt MEPS more rapidly, and ensured completion of transformation of products on the market within about 1.5 or 2 years and, considering the average service life of appliances, it is expected to achieve full market transformation within the next 10 years. The costs and benefits of transformation depend on many factors such as whether the country has a significant appliance manufacturing industry, size of manufacturing industry, international trade relations, level of awareness of supply chain and consumers.

The MEPS and Labelling regulatory framework, adoption of internationally consistent standards via transposition of European Union Directives, pro-active market surveillance, training and communications projects contribute a market transformation effort. At the halfway point of the project it has provided energy savings of 730 GWh corresponding to a GHG reduction of about 450,000 tons (t) CO₂. These figures are expected to reach about 3,700 GWh and 2.4 million tons (Mt) CO₂ respectively by the end of the project.

The Market Transformation of Energy Efficient Appliances in Turkey is a good example for other countries where no or little energy efficiency legislation is in place or no market transformation movement has been launched so far.

Governments need to underpin energy efficiency efforts with a level playing field of energy efficiency regulations for industrial equipment. MEPS and labelling policies have widespread global impact and target essential energy intensive equipment such as electric motors. Use of international standardization ensures alignment and access to global appliance markets for local industry. Regulatory action is measurable and deliberate. A regulated ‘level playing field’ enhances consumers and suppliers confidence to invest in higher efficiency products.

### Issue 4: Improving Transport Sustainability and Service Quality

#### Transport energy intensity

Between 1990 and 2014 transport energy intensity, including the sub-sectors road transport, aviation, rail and navigation, across the UNECE region improved from 20.4 to 12.3 MJ/USD. Transport energy intensity fell from 31 to 17 MJ/USD in North America and from 14 to 8.1 MJ/USD in Western and Central Europe. In Southeast Europe transport energy intensity fell from 8.8 to 8.0 MJ/USD. In Caucasus, Central Asia, Eastern Europe, and the Russian Federation it improved from 15 to 10 MJ/USD.

The sub-regional comparisons highlight transport productivity can vary across countries. North American energy intensity in 2014 was 17 MJ/USD while Western Europe’s was under half this energy intensity at 8.1 MJ/USD. Geographic differences make up much of this, as European cities and countries are closer and more compact with higher population densities and economic structures than their North American counterparts. Southeast Europe and Western Europe have nearly identical transport/GDP energy intensities, but the economic structures and transport systems are vastly different.

#### Vehicle fuel economy

Global transportation uses 93% of oil production, the balance of transport energy being electric rail and urban rail or electric bus systems. Apart from cities in Western Europe, most countries in the UNECE region are reliant on conventional fossil fuelled light duty vehicles for passenger transport, and fossil fuelled heavy-duty road vehicles for freight. Even with high levels of access to vehicles, mobility may still be constrained for some citizens. Affordability of efficient vehicles or fuel,
The United States achieved only a small 0.5% annual improvement in average fuel economy, marking a slowdown in improvement compared with the 2.3% average improvement over the 2012-13 time period. This reflects a tendency towards an increase in the average power of new vehicles and is consistent with the fall in oil and petroleum fuel prices.

Some countries from Western and Central Europe, Southeast Europe as well as Eastern Europe experienced average annual fuel economy improvements of 2% to 3%, which are much closer to the 3.6% improvement rate needed to meet the 2030 target of the Global Fuel Economy Initiative (GFEI)\(^\text{115}\), but still falling short of it. The continued improvement in fuel economy in Europe in 2015 is coherent with the weaker impact of changes in oil prices (due to the high fuel taxation regime applied in all European countries, changes in oil prices result in a lower percentage change in fuel prices).\(^\text{116}\)

In 2015, new LDV registrations in the Russian Federation totalled 3 million. The on-road stock of LDVs is estimated at 34 million in the same year. LDV ownership attained nearly 0.24 LDVs per capita, which is much higher than the average for other countries with comparable levels of personal income. Fuel economy is not regulated in the Russian Federation. However, the Russian Federation levies an annual circulation tax on vehicle owners, which increases progressively with vehicle power. From 2010, large vehicles experienced improving specific fuel consumption, limits to transport option and networks, and climatic extremes all limit mobility.

While the average fuel economy of vehicles continues to improve, the rate of progress has slowed in recent years. The average amount of fuel required to travel 100 km improved by 1.1% in 2014 and 2015, down from 1.8% between 2005 and 2008. The change reflects the composition of global car sales, as Light Duty Vehicles (LDV) sold in countries of North America as well as Western and Central Europe use less fuel than those sold in countries of the more Eastern stretches of the UNECE region including Caucasus and Central Asia, and suggests a technological gap in engine technology between the two regions. However due to the popularity of large, heavy and powerful vehicles in the United States, total fuel use per kilometre travelled in these countries remains greater than outside the OECD.\(^\text{113}\)

Fuel economy improvements in countries of Caucasus, Central Asia, Eastern Europe and the Russian Federation generally outpaced the countries in North America, as well as Western and Central Europe. This is a major change from the trends observed in previous assessments. There are two major reasons for this: trends occurring within specific markets, and effects attributable to market changes within OECD and non-OECD country groupings. Case study 9 provides more information.

### Case Study 9: The Global Fuel Economy Initiative’s (GFEI) Activities in Georgia, FYR of Macedonia and Montenegro.\(^\text{114}\)

GFEI is working with UNECE countries from the Caucasus, Eastern Europe, the European Union, North America, and Southeast Europe to promote improved fuel economy. Three examples for in-country work is provided below:

#### FYR of Macedonia

A summary of the relevant automotive fuel economy-related European Union Directives has been drafted and the Regional Environmental Center for Central and Eastern Europe (REC)’s office in the FYR of Macedonia, the local GFEI implementing partner, is collaborating with the Ministry of Economy, which is responsible for integration into the European Union. The automotive fuel economy baseline data collected and analysed to date with the Faculty of Mechanical Engineering includes data from 2005, 2008 and 2013. The FYR of Macedonia’s vehicle stock of registered vehicles has seen modest growth, with just over 350,000 vehicles total stock in 2013. The energy efficiency of the average vehicle improved over the years surveyed, from over 200 g CO\(_2\)/km in 2005 to below 150 g CO\(_2\)/km by 2013.

#### Montenegro

A first working group meeting has been held. The roles and responsibilities of the work group members have been allocated to: a) provide a review of national legislation and current policy (including taxation) related to fuel economy issues; b) identify key stakeholders and potential barriers to implement fuel economy policy; c) analyse the relevant European Union Directives that set vehicle emission standards; and d) set up a roadmap for transposition of these European Union Directives to national legislation.

#### Georgia

Georgia has completed a baseline (2008-2012), and a white paper on taxation has been submitted to government. The white paper stresses the need for taxation reform in order to improve the fuel economy of the automotive fleet. Analysis of the Georgian car fleet (both imported new and used vehicles) from 2008, 2010, 2011 and 2012 using the GFEI Fuel Economy Policies Impact Tool (FEPIT) has been carried out and a list of actions was produced that will inform the development of a national car fuel economy improvement plan in Georgia.

### Recent trends

Between 2014 and 2015, OECD countries improved their average fuel economy by 0.5%, compared with 1.8% from 2012 to 2013. This rate decline resulted from the combination of a weakening improvement trend in North America, continued improvements taking place in Europe, and market shares that have not experienced major changes in 2015.

- The United States achieved only a small 0.5% annual improvement in average fuel economy, marking a slowdown in improvement compared with the 2.3% average improvement over the 2012-13 time period. This reflects a tendency towards an increase in the average power of new vehicles and is consistent with the fall in oil and petroleum fuel prices.
- Some countries from Western and Central Europe, Southeast Europe as well as Eastern Europe experienced average annual fuel economy improvements of 2% to
with stagnation between 2012 and 2015. Medium-sized LDVs have seen a continuous decrease in specific fuel consumption since 2005, in line with the total average fuel economy. Newly registered small LDVs saw a deteriorating average fuel economy for most of the years since 2005. However, from 2012 onward this trend reversed, with a minor move towards improvement. Specific fuel consumption by powertrain also demonstrated contradicting trends. While diesels saw improving fuel economy, hybrid vehicles worsened. The trend seen in gasoline LDVs was reflected in total specific fuel consumption due to their high market share.117

**Issue 5: Improving Industrial Productivity with Energy Efficiency**

Industrial productivity and energy efficiency are closely linked. Energy efficiency measures helped to reduce energy use worldwide. Without the 13% improvement of global energy efficiency between 2000 and 2016, global final energy use would have been 12% higher.118 The achievements within energy efficiency are closely linked to improvements in industrial productivity.

As global populations and economies grow, the demand for energy intensive materials (metals, plastics, cement, pulp and paper) is expected to increase by between 45% and 60% by 2050, from 2010 levels.119 Many factors of production are at local paper) is expected to increase by between 45% and 60% by 2050, from 2010 levels.119 Many factors of production are at local

The concept of the circular economy – as opposite to the linear economy - is important in this regard, as it aims to keep materials and energy in use as long as possible, closing loops, and recover and regenerate materials including waste at the end of their life cycle. For example the economic value for waste to energy conversion was valued at USD 25.32 billion in 2013, and is estimated to be worth USD 40 billion by 2023.120 Improving the reduction, reuse and recycling of waste and materials further contributes to reduce greenhouse gas emissions (such as methane emissions from landfills) and reduces health and pollution related negative effects.

Between 1990 and 2014, industrial energy intensity across the UNECE region improved from 7.5 to 4.9 MJ/USD. Industrial energy intensity fell from 7.8 to 5.6 MJ/USD in North America, and from 4.7 to 3.5 MJ/USD in Western and Central Europe. In Southeast Europe industrial energy intensity fell from 5.3 to 4.1 MJ/USD. In Caucasus, Central Asia, Eastern Europe, and the Russian Federation it improved from 10 to 6.7 MJ/USD.

The Institute of Industrial Productivity estimates that energy management can reduce direct energy costs of individual businesses by 10-30%.121 Most industrial energy efficiency investments pay back in less than 3 years, largely because industry is focused on short-term risk and opportunities. For emerging economies, energy efficiency offers a strategic route to improved industrial productivity, an important driver for increasing wealth and welfare.

Industry energy efficiency contributes about 35% (144.5 EJ or 3452 Mtoe) of the total estimated energy savings from 2012 to 2035 in the IEA’s Efficient World Scenario. Additional investments of USD 0.7 trillion is required over this period but results in USD 2.2 trillion in fuel cost savings.122
Recognising the private ownership and competitive markets that most business exist in, a number of governments have developed industry – government voluntary partnerships to realise the potential for energy efficiency in industry. Case study 10 from Canada and the Netherlands highlights the nature and scope for energy efficiency improvement from energy management programmes.

**Energy management is central to progressing energy efficiency in industry**

All industrial processes can improve their energy productivity. ISO 50001 (like ISO9001, and ISO14001) establishes a framework for effective energy management processes so that businesses can identify, understand, and invest in energy efficiency projects that develop their businesses and improve productivity (see case study 11). After instituting cost-reflective energy prices, energy management is the most important and universally effective policy option for the industrial sector as in identifies economic opportunities for energy efficiency and renewable energy regardless of processes, and enables capabilities to make these investments. The success of any energy management system further depends on monitoring and verification of outputs and tracking that potential measures are efficiently implemented and followed through.

The UNECE Group of Experts on Energy Efficiency is currently examining ways to implement energy efficiency measures through a variety of activities.

### Case Study 11: ISO 50001:2011 Energy Management Systems

The ISO 50001:2011 Energy Management System provides the requirements for a framework for organizations to:
- Establish an energy policy;
- Allocate resources and create teams to implement an energy management system;
- Conduct energy reviews;
- Identify opportunities for improving energy performance;
- Establish baselines and energy performance indicators for tracking progress;
- Set energy performance improvement targets; and
- Implement action plans to achieve those targets.

Central elements of the standard include energy performance in operations, procurement and design, as well as an internal audit process to determine how well the organization is doing in implementing the system and achieving its targets. A continuous improvement process includes management review. An energy policy and energy planning process institute implementation and operation checking and controls. Information systems underpin energy management, using internal audits of the energy management system, energy monitoring, measurement and analysis to identify non-conformities, correction, corrective and preventive action for energy use and productivity.

### Energy management capacity building

To extend the application of energy management systems and decision-making capacity for energy efficiency investments, more organisations focus on the improvement of capabilities of energy managers within organisations as well as external energy auditors and advisors. For example, the United Nations Industrial Development Organisation (UNIDO) supports countries to improve industrial productivity, with energy efficiency being a central theme alongside cleaner production and environmental stewardship. It has developed an energy management system expert training programme that establishes a durable energy management capability in businesses. In line with training professionals in energy management, it is also crucial to provide human capacity development for policy makers, as they drive the development and implementation of relevant policies.

Furthermore, GIZ provides targeted trainings as well as train the trainer seminars for energy management, energy efficient buildings and performance, energy controlling and energy auditing, in a range of countries including the Ukraine and Turkey.

### 3.3.2 Opportunities and Prospects

**Market transformation: Renovating the building sector to renovate the buildings**

The construction sector tends to be highly decentralized and fragmented: building owners, designers, multiple suppliers and constructors, many dwellings are built by small builders with little access to efficient production techniques or modern building components that enable energy efficiency.

In rural areas there may be a large share of informal construction. Compliance with building codes is generally poor. These complex and uncoordinated markets are inherently more difficult to improve.

Applying regulatory controls and energy efficiency standards for buildings is unlikely to be effective when the capacity to respond is limited. UNECE has developed framework guidelines for energy efficiency in buildings and is undertaking a broad-based education and dissemination programme to address these challenges.
### Opportunity: Developing Supply Chain Capability for Renovation

Ramping up the innovation and competitiveness of the construction sector throughout the entire value chain increases the depth and rate of energy renovation. Successful programmes of deep energy renovation are feasible at a large scale if they are supported by policy measures, and more collaboration among actors. A set of ingredients must come together:

- Aggregation of demand; facilitators and integrators of technical solution packages;
- Advisory services that give power to customers; having "a la carte" options designed to fulfill users' needs and ambitious policy targets.
- Implementing support measures that encourage innovation and scaling up of deep energy renovation
- Establishing a harmonised energy renovation target at the European Union level and making public funding conditional on performance achieved is one of the key recommendations.
- Empowering frontrunners such as cities, regions or private initiatives to go beyond the set goals and lead by example accelerates the rate and depth of energy renovation.
- Public authorities should also lead by example and plan an integrated energy management approach to increase the energy performance of the building stock they own and occupy.

Building owners are not well informed about or motivated to ask for energy efficiency or comply with building energy efficiency standards. This is a general issue with new residential buildings. Only recently have commercial property owners started to recognise that the lower energy and operating costs and better rentals of energy efficiency buildings translate to increased capital value. As different building owners (such as public, private, investors, commercial, and institutional) have diverging interests in energy efficiency, different approaches are required to develop incentives and build awareness.

While much is made of the importance of energy efficiency building codes, they can achieve little in many countries without a deliberate effort to improve the capacity of the entire building value chain to deliver substantially new outcomes. Programmes like Netherland’s EnergieSprong that focus on transforming the building value chain as a system, work with all the decision makers in the system. Many building retrofit programmes undervalue the multiple benefits of energy efficiency initiatives. Health benefits in terms of reduced hospital visits, doctor's visits, prescription costs, and reduced sick days, can exceed the energy cost reduction significantly in some cases by 400%. The challenge is that these benefits have not always been well evaluated or considered, and countries vary in their drives for comfort and wellbeing in buildings.

### Opportunity: Transforming the Building Value Chain: EnergieSprong

EnergieSprong uses the social housing sector in each market as the Launchpad for these solutions, with a view to later scale to the private home-owner market. The independent EnergieSprong market development teams aggregate mass demand for high quality retrofits (and new built houses) in a market and, in parallel, create the right financing and regulatory conditions. With this structure in place, solution providers can go into a quick and transformative innovation process to deliver against this new standard.

The EnergieSprong refurbishment standard implies a renovation is completed within one week, without residents having to vacate the home. Moreover, it comes with a 30 (or 40!)-year warranty covering both the indoor climate and the energy performance. The refurbishment is financed by combining the energy costs savings from the tenants with the costs the social housing organisation saves on maintenance. Ultimately, residents get a better and more comfortable house without any additional monthly expenses.

In 2013, EnergieSprong brokered the “Stroomversnelling” deal between Dutch building contractors and housing associations to refurbish 111,000 homes to Near Zero Energy (NZE). Two years later, the Stroomversnelling network consists of contractors, component suppliers, housing providers, local governments, financiers, transmission system operators (TSOs) and other parties. Its goals are to reduce the price of Near Zero Energy renovations, increase occupants’ acceptance of these renovations and increase the momentum and growth pace of the NZE housing market itself. EnergieSprong programmes are now underway in France, the UK, Germany and New York State.

**Lessons learned.**

- Fix on a clear objective: ‘zero energy’ in the case of EnergieSprong.
- Ensure interventions deliver the full objective rather than incremental or partial changes.
- Ensure energy performance guarantees for refurbishments are financially more attractive than existing options.
- Employ a market transformation strategy to articulate initial mass-market demand using social housing stock. Use this to motivate:
  - Regulators to lift observed and unforeseen barriers,
  - Financiers to re-evaluate value propositions,
  - Builders to invest in better concepts and industrialized refurbishment or new construction packages.
- Work though programs with scale, avoid stand-alone projects unless they show how to structurally improve market conditions for E=0 programs.
- Mobilize collaborative programs where builders and suppliers share knowledge and work together.
A key multiple benefit is the reduction in public budgets from reductions in health and energy subsidies resulting from energy efficiency. Governments can recognise the public benefit from energy efficiency projects account for energy cost reductions in terms of cost of new supply, or export prices and add this to the private benefits regardless of the level of energy subsidies.

**Opportunity: The Economics of Building Energy Efficiency are more Compelling with a Societal Perspective. An example from Uzbekistan.**

Replacing non-standard and inefficient (also known as ‘homemade’) gas boilers in detached houses and small commercial buildings with efficient modern gas boilers could reduce gas consumption by about 2.4 billion m$^3$ per year, about 13% of the total gas consumption in residential, commercial, and public buildings in 2013. Enforcing the current building energy efficiency standards in the construction of new detached houses, which account for 99% of new residential construction, could cut heat energy demand of these new buildings by 50 percent, compared with those that do not implement the requisite energy efficiency measures. In schools and health care facilities, recent demonstration projects achieved over 40% reduction in space heating energy use through comprehensive thermal retrofit of buildings. All these energy savings can be attained with domestically available technology, products, and materials. They remain largely untapped primarily due to financial, institutional, and informational barriers. Replacement of the current stock of nonstandard gas boilers with modern gas boilers would require investments of about Uzbekistani Som 3.2 trillion, or about USD 1.2 billion at end of 2015 cost estimate and official exchange rate. The financial simple payback periods for residential and commercial consumers are about 6.6 and 5.2 years, respectively, based on the end of 2015 retail gas price. The simple payback periods are shortened to about 3.4 and 2.7 years, respectively, based on the end of 2015 export gas price.

### The "Avoid – Shift – Improve" approach to transport efficiency

The Global Fuel Economy Initiative has a ‘100 to 50 by 50’ objective of doubling the average fuel economy of new cars by 2030 and all cars by 2050.

While global average fuel economy improved by 1.0% on a yearly basis from 2014-15, this is 0.5% less than average improvement in fuel economy from 2010 to 2015 and around one-third of the improvement rate needed to meet the 2030 GFEI target. Of UNECE sub-regions only Western Europe was close to this range (2-3%). Most countries achieved less than 0.5% improvement. Small LDVs experienced deteriorating specific fuel consumption, while medium LDVs saw improving average fuel economy. Newly registered large LDVs gained weight between 2010 and 2015, but their average fuel economy did not change.

A combination of three strategies can limit transport energy growth to 5% above 1990 levels and reduce transport CO$_2$ emissions by 28%: 1) avoiding the need for travel; 2) slowing travel energy demand growth with better urban planning and demand management and adopting higher fuel economy vehicle and modes; and 3) shifting to lower energy travel modes like public and active transport.

A shift to electricity-based transport could deliver huge improvements in drive train efficiencies and open a way for renewable energy to meet transport energy demand. Most countries are ‘takers’ rather than ‘makers’ of vehicles, and while they take what is produced, global fuel economy standards oblige the production of more efficient vehicles. Recent slowing of vehicle fuel economy progress shows how much consumer prices and policy choices can shape transport intensity. Of the end-use sectors, transport is often the most neglected. While residential, commercial, and industry sectors have reasonably well developed policies, transport ministries are often distanced from the mainstream stationary energy efficiency efforts.

### Developing effective energy efficiency policies

Energy efficiency has a long way to go. No sector has reached even 50% of its efficiency potential. Between 60% and 80% of the global economic potential for energy efficiency is unrealized (see figure 3.2).

**FIGURE 3.2: Global Sectoral Energy Efficiency Potential.**

A range of policies have been developed and implemented within the UNECE region. Notably, the 2006 European Union Directive on Energy End-Use Efficiency and Energy Services (Energy Services Directive) requires Member States to submit NEEAPs in 2007, 2011 and 2014. NEEAPs set out estimated energy consumption, planned energy efficiency measures and improvements individual member countries of the European Union expect to achieve. In the first NEEAP, each Member State
should have adopted an overall national indicative savings target for end-use sectors of 9% or higher, to be achieved in 2016, and with an intermediate target for 2010.\textsuperscript{133}

Also ENOVA (Norwegian National Energy Agency), established 2001, works on energy efficiency improvement, production of energy from renewable energy sources, promoting new technology and enhancing general knowledge about the possibilities for using efficient, environmentally friendly energy solutions.\textsuperscript{134}

Table 3.4 summarizes the work to date in reviewing and developing energy efficiency policies and targets in UNECE member States.\textsuperscript{135}

As Table 3.4 indicates, a range of measures have been implemented until today. However, there is still a huge gap to realize the potential of energy productivity.

For example, it is estimated that doubling energy productivity would reduce global expenditures for fossil fuels by more than EUR 2 trillion by 2020. It would further contribute to the creation of more than six million jobs.\(^{41}\)

Table 3.5 summarizes the multiple benefits of increased productivity for different levels.

Sources: Derived from IEA (2014a) and IPCC (2014a).

To tap into the vast reserve of potential efficiency and renewable energy improvements, governments need to commit to sound governance. Current data from the ground need to be available and verified so as to provide the basis for the development of enabling policy frameworks that are realistic and lead to efficient investment decisions. An enabling framework of governance and financial policies remains the key challenge in most countries. At the same time, policies need to be flexible and adaptable in order to allow for continuous improvement as more data feeds back into them.

Figure 3.3 summarizes the scope of energy efficiency policies outlined in a UNECE report which highlights the need for a base of cross-sectoral policies as foundations for energy utility policies, an enabling finance system and operational policies in households, transport and business sectors.
Chapter III: Sustainable Energy in UNECE: Selected Issues and Country Case Studies

Best practices in policies can only be effective if they are fully applied in a local context. Policies that have worked well in one setting do not automatically work well in another. The examples that are offered in this report are concrete examples of policies and measures that are best in the settings for which they have been designed. All countries should reflect carefully on their respective development needs, the local conditions that need to be recognized and motivated, and the priorities for tailored energy efficiency policy.

### 3.4. Integrating Distributed Generation

Rapid technology advancements and the convergence of multiple disparate trends have already disrupted many industries and businesses, and there are signals that the energy sector may be next in line. A big shift in the way we produce or consume energy could disrupt energy markets as a whole, starting with power markets and snowballing from there.142

Technology has, and will continue, to provide completely new energy technologies for countries to exploit. In order to be able to benefit from these advances, a new set of energy policies and practices are required to enable integration of distributed sustainable energy options.143 144 These options are typically renewable energy sources, such as solar PV, wind, biogas, biomass, small hydro and geothermal energy, but can also include gas-fired microturbines. Many features of renewable energy make them difficult to integrate into existing energy infrastructure, either the national transmission grid or local distribution networks.

In many countries, energy efficiency, renewable energy, access and affordability are treated as separate policy streams, often managed in separate agencies and budgets and separate from more mainstream energy policy and planning. New paradigms of demand and asset management, system optimisation and integration are needed which are adaptive and resilient. Countries that recognise this and support the achievement of SDG outcomes can anticipate significant multiple benefits and spill overs delivering broad socio-economic and environmental benefits.

#### 3.4.1. Selected Issues and Country Responses

This section focuses on the integration of variable renewable energy which provides challenges for grid integration and current power market design regimes. It further discusses the opportunities provided by distributed renewable energy for remote communities. Case studies are presented for the Ukraine, Denmark and Croatia.

### Issue 1: Integration of Variable Renewable Energy: The Need for Flexible Supply and Better Market Design

Integrating “variable” or “intermittent” renewable energy (VRE), notably solar and wind, into the energy mix creates challenges for transmission and distribution. Countries are adapting to growing shares of VRE in their energy systems, notably Denmark, Germany, and Spain. Market design and operations are being adapted to enhance integration of VRE and provide the necessary balancing on the grid.

The existing institutional and technological infrastructure in most UNECE countries was designed to use fossil fuels with a base load model. It is not obvious how to upgrade and convert these systems to include renewable energy. One of the challenges is how existing energy systems, which assume fuel storage and on-demand availability, can adjust to accommodate VRE.

<table>
<thead>
<tr>
<th>Case Study 12: Integrating Variable Renewables into Grids.145</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>VRE electricity deployment and integration develops over four stages. Each stage has its own specific characteristics and operational priorities.</strong></td>
</tr>
<tr>
<td>Firstly, wind and solar plant output are subject to daily variations in power demand. Annual variable renewable electricity shares are limited to around 3% of annual electricity generation. Secondly, operational practices, such as intelligent forecasting of variable renewable electricity output, are introduced. UNECE countries in this phase include the Netherlands, Sweden, Austria, and Belgium. They have variable renewable energy electricity shares ranging from 3% to almost 15%.</td>
</tr>
<tr>
<td>In the third phase variability affects overall system operation, including that of other power plants. In this phase power system flexibility is paramount. The power system must accommodate substantial uncertainty and variability in the supply-demand balance. The two main flexible resources to date are dispatchable power plants and the transmission grid but demand-side options and new energy storage technology are growing in importance. Countries in this phase include Italy, the United Kingdom, Greece, Spain, Portugal, and Germany, with VRE electricity shares ranging from 15% to 25%.</td>
</tr>
<tr>
<td>The fourth and final phase sees “highly technical” and “less intuitive” challenges that require resilience in the face of events that could disturb normal operations on very short time scales. Only Denmark and Ireland can be considered to be facing these challenges, with variable renewable electricity share ranging from 25% to 50% in annual generation.</td>
</tr>
<tr>
<td>Countries with historically high hydroelectricity shares in their power systems like Norway have been early adopters of policies and market techniques that manage annual hydroelectricity variability.</td>
</tr>
</tbody>
</table>
Economic Council report, “The Future of Electricity”, highlights how subsidies while investors receive poor price signals for energy, policies like FiTs or renewable energy subsidies. Indeed, to offer economic investments than typical renewable energy support distributed renewable energy and are more durable signals for of demand and supply in real time are key drivers for successful investments in distributed renewable energy. The interaction of energy and capacity price signals that motivate economic market policies. Distributed generators should receive of distributed renewable energy requires enabling energy resources.

Case studies 12 and 13 show that the successful implementation of distributed renewable energy requires enabling energy market policies. Distributed generators should receive energy and capacity price signals that motivate economic investments in distributed renewable energy. The interaction of demand and supply in real time are key drivers for successful distributed renewable energy and are more durable signals for economic investments than typical renewable energy support polices like FiTs or renewable energy subsidies. Indeed, to offer subsidies while investors receive poor price signals for energy used or generated can create perverse outcomes. The World Economic Council report, “The Future of Electricity”, highlights that achieving renewable energy requires clearer policies to encourage economic investments.

Distributed renewable energy can enhance an energy system’s resilience and provide improved energy access in countries that do not have sufficient energy resources for their economic development. Although fuel wood and processed biofuels can be stored, most other renewable energy has diurnal or seasonal availability. Therefore VRE need a backup, either supplied from the grid or a local battery or alternative generation system. The scale of the backup power supply depends on the size of demand peaks and their coincidence with the available VRE resources.

Case studies 12 and 13 show that the successful implementation of distributed renewable energy requires enabling energy market policies. Distributed generators should receive energy and capacity price signals that motivate economic investments in distributed renewable energy. The interaction of demand and supply in real time are key drivers for successful distributed renewable energy and are more durable signals for economic investments than typical renewable energy support polices like FiTs or renewable energy subsidies. Indeed, to offer subsidies while investors receive poor price signals for energy used or generated can create perverse outcomes. The World Economic Council report, “The Future of Electricity”, highlights that achieving renewable energy requires clearer policies to encourage economic investments.

Some of the first investments in renewable energy occurred in remote communities to address social needs and local development agendas with renewable energy because of constraints in traditional energy resources.

Over time, community-developed renewable energy supply expanded and the concept of energy-independent villages evolved, particularly in Western and Central Europe. For example, a series of villages in Germany, most famously the 150-person village “Feldheim”, produce sufficient amount of renewable energy to cover its own energy demand, while selling overproduced energy from the 122.6 MW wind, solar and biomass capacities back to the national grid. Essentially, rather than being off-grid, the energy dependence of these villages is enabled through the connection to the national grid as it helps to compensate for the intermittency of VRE.

On 6 April 2017 the Ukrainian parliament submitted Draft Law No. 4493 of 21 April 2016 on Electricity Market (the “Electricity Market Draft Law”). The Draft Electricity Market Law introduces responsibility on generators for managing the hourly imbalances in the day-ahead market where they will sell electricity at “green” tariff rates.

It is planned that the responsibility for solar and wind will be introduced gradually with increases by 10% annually starting in 2021 until 2030 with 10% tolerance for wind and small hydro (the tolerance margin for small hydro will be valid until 2025) as well as 5% tolerance for solar. It also envisages the possibility of signing preliminary power purchase agreements before construction when a producer of electricity from renewables has executed title documents in respective lands, obtained a construction permit or executed a similar document under Ukrainian laws and signed a grid connection agreement.

The producers of electricity from renewables which have commissioned their power plants before the entry into force by the Electricity Market Draft Law are exempt from liability for imbalances until 2030.

On 6 April 2017 the Ukrainian parliament submitted Draft Law No. 4493 of 21 April 2016 on Electricity Market (the “Electricity Market Draft Law”). The Draft Electricity Market Law introduces responsibility on generators for managing the hourly imbalances in the day-ahead market where they will sell electricity at “green” tariff rates.

It is planned that the responsibility for solar and wind will be introduced gradually with increases by 10% annually starting in 2021 until 2030 with 10% tolerance for wind and small hydro (the tolerance margin for small hydro will be valid until 2025) as well as 5% tolerance for solar. It also envisages the possibility of signing preliminary power purchase agreements before construction when a producer of electricity from renewables has executed title documents in respective lands, obtained a construction permit or executed a similar document under Ukrainian laws and signed a grid connection agreement.

The producers of electricity from renewables which have commissioned their power plants before the entry into force by the Electricity Market Draft Law are exempt from liability for imbalances until 2030.

Case Study 14: Wind Turbine Cooperatives in Denmark.

Jointly owned wind turbines in Denmark are organised as partnerships with joint and several liability. In practice, the risk of joint and several liability is minimised in that the partnership is unable to contract debt. This is ensured in their bylaws which maintain that the partnership cannot contract debt and that the turbines must be adequately insured. Partners own a part of the wind turbine corresponding to the number of shares bought. Often one share is calculated as corresponding to the yearly production of 1000 kWh from that particular wind turbine.

Private individuals and cooperatives have played an important role in the development of the Danish wind energy sector. 15% of the Danish wind turbines today are owned by about 300 cooperatives.

Local acceptance of a wind turbine project is necessary. Public resistance against wind turbines in the landscape has been, and still is, one of the largest barriers to the development of wind power. Opinion polls show a wide support in the population in favour of wind power in general. However, uncertainties and lack of information in the planning phase of future wind power projects often give raise to local scepticism. The experiences from a number of wind energy projects in Denmark show that public involvement in the planning phase and co-ownership increases the acceptance. Adding to this, two private offshore projects show that cooperative development and ownership is also an option in larger-scale projects.

The Middelgrunden Offshore Wind Farm (40 MW), close to Copenhagen, was developed though cooperation between the municipality, an energy company and, not least, a number of private individuals. Middelgrunden is the world’s largest cooperatively owned wind farm with more than 8000 members of the cooperative. The Samsø project off the east coast of Jutland (23 MW) was developed by a cooperative with local people on the island of Samsø and the municipality as members.
Some countries, despite their significant cost-effective fossil fuel reserves, have set ambitious goals for renewable energy. Their ability to pursue these goals hinges on power system and investment capabilities and on their available renewable energy resources. Not all countries are starting their energy transitions with an enabling set of renewable energy potentials.

### Realising available renewable resources

Underlying climatic and geographical contexts are substantial considerations in a country’s primary renewable energy resource potential. In terms of solar energy, the UNECE region is characterised by a low insolation resource in the range of 700 to 1200 kWh / kilowatt peak (kWp) for most countries. The United States has the highest potential, almost reaching 2000 kWh/kWp, followed by Central Asian countries, in particular Tajikistan and Turkey, and afterwards followed by Spain, Italy, and Armenia. Even countries with low insolation levels such as Germany can install solar PV on a large scale. At the end of 2016, the total nominal PV power installed in Germany was 41 GW, distributed over 1.5 million power plants. Initiatives to track renewable energy source potentials exist, such as the Global Wind Atlas by the International Renewable Energy Agency (IRENA). It indicates that there is ample potential in different sub-regions of the UNECE region, in particular in coastal areas along Western and Central Europe, as well as the North American coast. A similar global map for bioenergy does not yet exist but many national assessments exist, such as the Biofuels Atlas for the United States provided by the National Renewable Energy Laboratory (NREL) and a Bioenergy Simulator by IRENA.

Some countries start from a very low base to pursue significant renewable energy targets. Kazakhstan for example has a 1% renewable electricity share and objectives of 3% by 2020, 10% by 2030, and 50% renewable energy by 2050. As an oil and gas exporting country, a range of support mechanisms and investment incentives need to be put in place in order to utilize the country’s renewable energy potential. These offer distributed clean energy solutions in particular for rural areas where 47% of the population live.
Some countries with existing substantial renewable energy capacity face challenges to extend from their traditional centralised renewable energy systems to new renewable and more distributed energy opportunities. The ability to invest in renewable energy and trade renewable energy outputs across borders is therefore important for many countries and can liberate further economic improvements in renewable energy costs for some countries.

An electricity market evolving to meet the dynamic challenges of distributed power

Electricity markets are already moving their focus towards consumers. There is talk of the “prosumer” who not only consumes electricity but also produces it, for example through roof-top solar panels. The shift is important for network companies who must balance growing distributed VRE capacity while selling lower volumes of electricity. One of the common barriers to change is that the power system has been technically driven and requires a centrally designed planning system to operate effectively because the physics of power systems demand instantaneous response to changes in demand and supply. The reality is however that our ability to measure and understand system dynamics in real time has evolved in the past 30 years. Technical options have evolved away from a central plant investment model towards distributed systems.

A distributed energy transformation, based on demand side energy efficiency and distributed renewable energy, will address the issues of access quality, affordability and system resilience for less cost and lower environmental impact than most supply security options.

New conventional energy supply has been perceived by policy makers as reliable and secure. However there is growing evidence that addressing end-use efficiency is not only cheaper than new supply options, but that it also delivers large multiple social and economic benefits at lower cost than traditional supply options. This is particularly so in countries with inefficient or unaffordable heating services. Here the value of improved comfort and reduced health costs can exceed the value of reducing energy demand and energy efficiency investments. Indeed in the coldest continental climates e.g. Kazakhstan and the Russian Federation, the demand for heat is highest and scope for renewable energy is limited.

A shift in thinking to a system maximising the value to society rather than the current focus on lifecycle cost of renewable energy (and other) supply options is required for improved service provision, energy system economics, and energy resilience.

Opportunity: A Move from Levelised Cost of Electricity to System Value.

As legacy power systems face disruption from new technology and resources the underlying costs drivers start to shift from simple indicators to more complex metrics. The traditional focus on the levelised cost of electricity (LCOE) is no longer sufficient. Next-generation approaches need to factor in the system value of electricity from wind and solar power.

System value is defined as the overall benefit arising from the addition of a wind or solar power generation to the power system. It is determined by the interplay of positives and negatives. Positive effects can include reduced fuel costs, reduced CO₂ and other pollutant emissions costs, reduced need for other generation capacity and possibly grid infrastructure, and reduced losses. On the negative side are increases in some costs, such as higher costs of cycling conventional power plant and for additional grid infrastructure, as well as curtailment of VRE output due to system constraints. System value provides crucial information above and beyond generation costs; in cases where system value is higher than the generation cost, additional VRE capacity will help to reduce the total cost of the power system.

As the share of VRE generation increases, the variability of VRE generation and other adverse effects can lead to a drop in system value. It is important to distinguish the short-term and long-term system value of VRE. In the short term, system value is strongly influenced by existing infrastructure and the current needs of the power system. For example, if new generation is needed to meet growing demand or retirements – as in South Africa – system value will tend to be higher. By contrast, the presence of large amounts of relatively inflexible generation capacity – as is the case in Germany – can lead to a more rapid system value decline in the short term. For long-term energy strategies, the long-term system value is most relevant. This accounts for both fuel savings and capital investments. In order to attract investments in VRE at lowest cost, policy mechanisms are needed that provide sufficient long term revenue guarantees to VRE investors. In turn, such mechanisms need to be designed in a way that accounts for the differences between systems of using different generation technologies. Existing policy practice already provides a number of ways in which the value of VRE can be boosted by facilitating system-friendly deployment strategies.
Regardless of current energy market structure, renewable energy, whether centralised or distributed, require durable signals that give investors clearer insight into the drivers for new capacity, and offer a reliable basis for investment evaluation and return over the life of the investment. This applies whether the investor is an urban householder, a farmer, a business or professional power plant investor. Their motivation to invest is similar - a reliable return on the renewable energy installation.

3.5. Improving Supply-Side Sustainability in Generation and Transmission

Naive perceptions of security of supply persist in many countries. Security is perceived to be enhanced by self-sufficiency, often through new domestic supplies of fossil fuels, while energy trade is perceived as unreliable and renewable energy is perceived as variable and challenging to system stability (stability is different to security of supply). The institutional paradigms and policies that served well over the past 50 years are now challenged by a wider range of renewable energy and demand side products and services.

3.5.1. Selected Issues and Country Responses

Incumbents in any market have a position of strength based on experience in the market place and a history of shaping and working with the policies and practices in the market. The incumbent generally represents inertia to change due to its business model and the desire to obtain economic rents from sunk capital. The high reliance on fossil fuels and the associated infrastructure in many UNECE countries act as a mass that is very difficult to shift.

A range of issues are considered in this section including the high share of fossil fuels in power generation and the need to improve generating efficiencies. Other issues include the implications and opportunities of energy security driven policy making in the UNECE region, and scaling up of grid-connected renewable energy.

Issue 1: A Unsustainable and Continued High Reliance on Fossil Fuels

UNECE countries depend on fossil fuels for 80% of their energy supply. Coal provides 18% of TPES in the region, less than its global share of 29%. Compared to other...
The use of fossil fuels has shaped the institutional and technological infrastructure that we use today. It is difficult and expensive to upgrade and convert to renewable energy operation.

There is a locked-in dependence on fossil fuels, often with poor efficiencies. A transition away from this is neither obvious nor easy.

Many fossil fuel based economies, developed as well as emerging economies, rely heavily on energy imports. Germany (64%), Armenia (72%), Belarus (88%), Georgia (70%) and Moldova (90%) are reliant for more than 60% of their TPES on fossil imports.  

Overall, fossil fuel shares remain high in countries. For example, in Germany the share of fossil fuels in TPES remains high (80%), despite the Energiewende efforts under way. This is because fossil fuels have advantages. They are comparatively dense energy carriers and are easy to trade, both regionally and globally. Renewable energy does not have these attributes.

However, the fossil fuel infrastructure is aging in most countries and this represents a window of opportunity for change. Those countries that have managed to reduce their fossil-to-TPES ratio to date have had a number of aligned drivers in place for change:

- Economic and fiscal robustness enabling access to and investment in efficient plant to meet demand growth and replace aging plant,
- Competitive energy markets, with cost-reflectivity that rewards investment in improved efficiency,
- Policies to reduce environmental impacts,
- Alternative resources (gas, nuclear, renewables).

For countries with more than 80% fossil fuel share of TPES, one of more of these change drivers has been absent. In most cases countries can alter the first three drivers given time. However, despite the global commitments to advance sustainable development, accessing alternative resources and technology is a real constraint for many countries. While new renewable energy options enable further renewable energy growth, they tend to be distributed and require markets that incentivise consumers to adopt them.

The transition from a fossil to a low carbon energy system is difficult and requires substantial effort across policy, structure, finance and technology.

### Issue 2: Inadequate Progress in Supply Sector Efficiency of Fossil Fuel based Generation

The efficiency of conversion and transformation from primary to final energy is an important aspect of SDG 7. Increasing efficiency reduces costs and greenhouse gas emissions. The ratio of final to primary energy reflects overall energy efficiency in the supply sector. A gradual reduction in this ratio has occurred globally from 72% in 1990 to 68% in 2010. This implies a reduction in conversion and transformation losses.

In the UNECE region the ratio dipped by around 1.4% during the same period but remained higher at 71% than the world’s average 68% (2010). In 2015 the ratio was 68%. In 2014, 41% of global electricity generation came from coal-fired power plants and 22% came from gas power plants.  

### Efficiency of thermal power plants

Changes in power production fuel mixes are driving the reported average plant efficiencies. The share of coal in the global power generation mix will drop to 36% by 2021, down from 41% in 2014, driven by lower demand from China and the United States, fast growth of renewable energy and a strong focus on energy efficiency.

The share of fossil fuels in the UNECE region’s power generation sectors varies from 2% to 100%. 6 countries have less than 3% fossil fuel shares in their power systems (Albania, Norway, Switzerland, Tajikistan all with large hydro resources, Iceland with geothermal, and France with nuclear). Denmark and Germany have achieved fossil fuel shares of 40% and 57% respectively. Eight countries have power systems based on more than 90% fossil fuels, including Kazakhstan 92%, Cyprus 93%, Azerbaijan 94%, Moldova 94%, Malta 97%, Israel 98%, Belarus 99%, and Turkmenistan 100%.

Coal is the dominant fuel (30%) for power production in the UNECE region, followed by gas (25%) and nuclear (21%). Hydro power follows at 15%. Power generation is responsible for 40% of global CO₂ emissions, and the power sector in UNECE region contributes a substantial amount of the region’s emissions. Coal’s higher carbon intensity and the lower efficiency of coal power plants results in comparatively higher emissions.  

In 2014 coal accounted for 73% of global electric sector carbon dioxide emissions, and gas accounted for 20% of global power plant carbon dioxide emissions.

The average power plant efficiency of electricity generation from of fossil fuels (coal, gas and oil) in the UNECE region improved from 36% in 1990 to 41% in 2014. Gas fired generators improved from 37% in 1990 to 49% in 2014, the highest amongst regions.

Using in-house power plant data systems, GE evaluated the scope for power plant efficiency upgrades and the impact on emissions. Tables 3.7 and 3.8 outline the estimated technical (not economic) potential for efficiency improvements to coal and gas power plants in key UNECE member countries from GE’s analysis.
TABLE 3.6: Coal Power Plants: Potentials for Efficiency Improvements and Emission Reductions.

</table>

In the UNECE countries that rely on fossil power generation, it would be possible to reduce CO₂ emissions by 542Mt through upgrades.

83% of the potential is in coal power plants. Two thirds of coal plant improvements are in turbine and boiler hardware upgrades, with the remaining third in operational data and software improvements.

55% of the gas plant improvement potential is in turbine and boiler hardware upgrades and 45% in data systems.

Besides supply side efficiency, losses in electricity transmission and distribution declined from 8.2% in 1990 to 7.2% in 2014, the lowest amongst the regions. Natural gas transmission and distribution fell by half from 1.2% to 0.6%.\(^{172}\)

Despite the declining costs of renewable energy (see figure 3.4) per Megawatt hour (MWh) of renewable energy produced and rapid growth in implementation, challenges exist to maintaining progress and realizing the potential of renewable energy.

Key challenges include the continued lack of supportive, long term sustainable energy policies, the lack of investments and support by domestic banks in many countries with less renewable energy implementation experience, the shortage of specialists and geo-political factors that maintain conventional energy subsidies, constrain trade and maintain the lock-in of older inefficient fossil energy infrastructure.
Policies that support renewable energy have evolved significantly over the past decades. While initial support mechanisms focused on FiTs guaranteeing a fixed tariff for supplied kWh over a fixed period of time, more effective and efficient support policies have developed over time. In particular the move to renewable energy auctions seeks to address the need for renewable energy to become competitive.

A summary table of the renewable energy policies implemented within the UNECE member States is provided in Annex VI. Most countries in the UNECE region have established renewable energy policies.

- Bulgaria, where the Energy from Renewable Sources Act (ERSA) and the Energy Act (EA) enables preferential prices for electricity from renewable sources. The regulator set FiTs for electricity produced by new renewable electricity installations and for biomass. Renewable electricity can be sold at freely negotiated prices and/or into the balancing market.
- Ukraine’s 2014 National Renewable Energy Action Plan aims to implement a series of renewable energy policies - such as preferential loans for alternative energy production, tax exemptions, accelerated depreciation, import duty waivers - as well as initiatives eliminating fossil fuel energy subsidies for residential users.
- In 2015, the government of Belarus set new FiTs for renewable energy power fed to the country’s grid. Tariffs range from 1.1 to 3.3 USD-cents per kWh for the first 10 years to 0.45 USD-cents per kWh after 20 years. In addition, based on a program with performance targets to increase biodiesel production from 2007-2010 by utilizing domestic resources, liquid biofuels consumption increased from zero in 2007 to 0.0010 EJ in 2014.

Figure 3.5 provides the percentage share of policy types implemented across the 56 member States. Three quarters of countries have introduced renewable energy shares in final energy and about two thirds have defined renewable energy targets as share in electricity generation.

Among regulatory policies, the most prominent mechanism remains the FiT or premium payment, despite its economic inefficiency, which 45 countries (re-)introduced for one or more types of renewable energy sources. Transport obligations for biofuels as well as tradeable renewable energy certificates were the second and third most common choices.

Less used are electric utility quota, net metering regulation, or heat obligations. The use of renewable energy auctioning increased. Sixteen countries introduced auction schemes for renewable energy. Notably Spain, which terminated its FiT scheme in favour of an auction scheme for different types of renewable energy. Also Germany is increasingly moving from FiT to auctions as shown in case study 16.

Source: UNECE (2017a) for 17 countries, otherwise from REN21 (2017).
Case Study 17: European Energy Security: Improving Import Dependency.

18 European Union member States import more than 50% of their energy. Demand for energy is now more than 8% below its 2006 peak due to structural changes in the economy of the EU, the economic crisis and efficiency improvements linked to policies of the past 10 years. Import dependency, reached more than 50% as European production declined after 2006, but stabilised thereafter with increasing renewable energy production and demand reduction. In 2012, oil was at 90% import dependency, gas at 66% import dependency and coal at 42%. Import dependency for uranium is 95% but it is a relatively small quantity.

Oil supply risks are off-set by high market liquidity and regulated 90-day stock holdings.

Gas import pipeline capacity is 8776 GWh/day, LNG terminals 6170 GWh/day. Long term pipeline gas contracts, nearly entirely with the Russian Federation, are estimated to cover 17-30% of market demand. Gas market and gas infrastructure (interconnectors, reverse flows and storage) developments are improving resilience. However the Baltic States, Finland, Slovakia and Bulgaria remain dependent on a single supplier and the Czech Republic and Austria have very concentrated imported gas supplies. A winter supply disruption through Ukraine transit routes would pose challenges for Bulgaria, Romania, Hungary and Greece.

Coal provides 17% of energy in the European Union, used in electricity, CHP and district heating plants, with Germany, Poland, the United Kingdom and Greece being the top four consumers. Coal demand declined by 20% from 1995-2012 in nearly all Member States. Import dependency currently stands at 42% and has been increasing due to the closure of uncompetitive mines in a number of member countries of the European Union.
United States has about 200 trillion cubic feet of proved shale gas resources in 2014. In ‘Revolution Now’ the United States Department of Energy describes the rapid price declines and uptake of wind, solar photovoltaic, LED lighting and electric vehicles as an “historic shift to a cleaner, more domestic and more secure energy future is not some far-away goal. We are living it, and it is gaining force”. In the United States, solar energy accounted for 32% of the nation’s new generating capacity in 2014, beating out both wind energy and coal for the second year in a row.

Oil

From 2011 to 2015, oil prices were sustained on average over USD 100 per barrel (USD/bbl), a sustained price level previously only seen as price peaks. Prices fell during 2015 to 37 USD/bbl, while OPEC held back production. Global production exceeded supply by an average 2 million bbl/day during 2015.

The United States remained the largest consumer at 21%; Europe, 15%; Russia, 3.7%. Main net exporters of oil within the UNECE region are the USA, Norway, and the Russian Federation.

Oil demand decreased 13% in the period 2005-2012 but continues to be 34% of the primary energy source used in the European Union. 64% of final consumption of oil is used in transport where electric vehicles are now looking like a viable alternative. Oil retains the highest import dependency, 88% (80% if only imports from outside the European Economic Area are taken into consideration), and significant import bill (EUR 302 billion in 2012).

Natural gas

The European Union relies on natural gas imports for 66% of its gas supply. The European Union’s long-term contracts for pipeline gas supply cover 17-30% of the European Union’s market demand, are nearly entirely imports from Russia, and are sometimes covered by long term inter-governmental agreements, some of which extend to 2030.

The total capacity of pipelines to the European Union from supplier countries is 397 billion cubic meters per year (bcm/year). New projects under construction include the pipelines of the Southern Gas Corridor, which will allow by 2020 supplies to markets of the European Union of a further 10 bcm per year gas from Azerbaijan. The envisaged infrastructure in Turkey could transport up to 25 bcm per year to the European market allowing further gas volumes from Azerbaijan as well as Northern Iraq.

130 underground gas storage facilities in Europe, including non-European Union countries such as Turkey, comprise a combined capacity exceeding 90 bcm. Regasification capacity of liquefied natural gas (LNG) terminals in the Europe (excluding small scale LNG) is 200 bcm/year, half the European Union’s annual gas imports of 400 bcm in 2015. Further terminals are planned and their total capacity is planned to reach 275 bcm/year in 2022.

The main net exporter of natural gas in the UNECE region are the Russian Federation, the USA, and Norway. While much of the UNECE regions gas is distributed by national and regional pipeline systems, the bulk of global trade is increasingly shaped by LNG system dynamics. Global LNG supply capacity is 300Mt/year but in 2016 only 268 Mt were traded. Buyers in Asia (which makes up 70% of global LNG demand) are shifting from fixed long-term contracts with a priority on security of supply, to more flexible group purchase of short term gas and spot contracts driven by power sector flexibility and deregulation. The United States is likely to be the third largest supplier in 2018, and its flexible terms are likely to be attractive to Asian buyers.

In Europe the 2013/14 winter supply outlook of ENTSOG noted that there were no big variations in Norwegian, Algerian or Libyan supplies, but that there were important decreases in LNG imports (- 32%). The drop in imports of LNG was a result of a divergence of gas prices between Europe and Asia, which led cargos to be redirected to Asia and reducing the arrival of spot cargos in Europe. The drop was replaced by draws on storage (+40%) and increased Russian imports (+7.5%, mostly Nord Stream flows).

LNG export capacity is still growing (US and Australia) and stagnant demand is suppressing gas spot prices. European gas demand not covered by long-term supply contracts has a strong negotiating position.

Coal

Coal is a low cost, low-grade fuel and a rich chemical feedstock. In 2014, it provided 29% of the world primary energy, but created 46% of global GHG emissions and a disproportionate amount of local air and water pollutants. Disruptive streams of low cost gas (growing LNG supply and lower prices) and renewable energy are eating away at coal’s share of demand, but it nevertheless remains locked in to its historical low cost paradigms and infrastructure.

The IEA points to coal being 27% of global energy by 2021. The United States’ and European coal demand was 47% of global coal trade in 2000, but this has now dropped to 22%. Coal’s role in the developed world’s existing power and heat infrastructure is declining. Lack of investments in CCS technology further hinders development of coal-based technology. However, coal remains the mainstay in many emerging economies.

The United States and the European Union are respectively the second and third largest coal-consuming regions in the world, using 25% of global coal production. United States coal supply is almost entirely domestic, and coal consumption dropped 15% in 2015. The European Union meets only about one third of its needs for hard coal with indigenous production.
Demand for solid fuels in the European Union has declined by almost 20% since the mid-1990s. Following the slump in consumption in 2009, demand started recovering and 2012 was the fourth consecutive year of growth in solid fuel consumption. A number of Member States have seen a double-digit growth in consumption between 2011 and 2012, in particular Portugal (+32%), Spain (+20%), France (+13%), Ireland (+12%) and the Netherlands (+10%). The decline in coal and CO\textsubscript{2} prices and high gas prices provided coal with a strong competitive advantage to gas in power generation.

The European Union has a diversified portfolio of coal suppliers, with Russian, Colombian and United States imports each accounting for approximately a quarter of hard coal import quantities. Rising production costs of domestic hard coal and depressed prices on global coal markets have made imports an economically attractive option. International prices increasingly serve as leverage to negotiate price contracts with domestic coal producers.

Global coal markets are competitive and have not experienced the spikes or disruptions observed in the crude oil market or regional markets for natural gas. There is no minimum stock requirement in terms of coal inventories and stock changes almost daily.

The current global situation of low coal prices and stagnant global demand is contrasted with significant pressure and change in countries where coal is in a period of intense disruption. Countries carry individual accountability to reduce emissions, so they must improve the economics and efficiency of a vast stock of older coal-fired power plants. New investments in renewable energy challenge the underlying cost structures that have developed the current fleets of power and heat plants.

**Issue 5: The Difficulty of an Energy Transition Paradigm Shift**

The term ‘energy transition’ describes a shift over the medium term to a mix of energy efficiency, low carbon options and universal access to quality energy services.

Today an energy transition is under way and change in the global energy system is observable. Renewable generation excluding large hydro accounted for 55.3% of newly added electricity generation in 2016, and produced an estimated 11.3% of total global electricity generation (with a total share in installed capacity of 16.7%). Most of the new generating capacity installed in 2016 came from solar power, followed by wind, coal, gas, large hydro, nuclear and biomass.

The overall increase in the world’s nuclear net capacity in 2016 was the highest since 1993, with new reactors coming online in China, the United States, South Korea, India, the Russian Federation and Pakistan. Conversely, Germany, France, and Sweden have announced their intention to withdraw from or reduce nuclear power. In the future capacity additions will be offset at least in part by retirements.

Coal demand fell worldwide but the drop was particularly sharp in the United States, where coal demand was down 11% in 2016 because of price competition with natural gas. In the United States electricity generation from natural gas was higher than from coal.

In the European Union, gas demand rose about 8% and coal demand fell 10%, keeping emissions largely stable last year. Renewable energy also played a role. The United Kingdom saw significant coal-to-gas switching in the power sector, as a result of both cheaper gas and a mandated carbon price floor.

**Energy transition dynamics**

While current progress looks promising, there is much more to do before a durable energy transition is confirmed.

Many countries still focus on energy security based on indigenous, typically fossil, energy resources. While 10 UNECE countries are major exporters of energy resources to global markets, strong regional and cultural behaviours persist in an on-going reliance on indigenous resources. Developing a more sustainable energy system requires a shift in the view of security of supply. Economic trade in sustainable resources, increasing demand side focus and innovations in technology and skills will shape sustainable outcomes and produce an adaptive and resilient energy system.

Existing plants, can continue operating despite lower efficiencies because they simply have to cover their cash costs. Their initial investment capital was amortised years ago and they can act as marginal operators.

Although many countries have already expended effort in ‘priming’ renewable energy with FiTs and have grown renewable energy from a negligible base, they have yet to alter their vastly greater, existing coal systems. A notable example is found in Germany where there has been little change in the efficiency and scale of coal fired capacity.

The challenge is to discern investment pathways that enable an economically efficient transition that is fast enough to meet the 2030 Agenda.

The risk of not participating in the energy transition are high. Countries, may have the financial wherewithal and the technology to deploy high-efficiency, low-emission coal technology but risk stranding investments if competitive gas and renewables displace new coal (see also case study 18).

The transition will neither obvious nor easy but a process of moving power systems to high efficiency gas and renewable energy is do-able both technically and economically. Placing a real price on carbon would reinforce the drivers and accelerate the transition.
Restructuring

Markets for energy and utilities that are transparent, competitive and facilitate efficient cost-reflective pricing are a pre-condition for delivering timely, innovative and least cost responses to achieve public policy goals.

The Russian Federation is undertaking one of the most ambitious electricity reform programmes in history making impressive progress by international standards, transforming the sector into a key driver of longer-term economic prosperity (see case study 19). The Russian Federation unbundled and privatised its generation infrastructure USD 30 billion generation assets were unbundled and privatised from 2005), instituted incentive-based economic regulation, and established an investment obligation mechanism targeting new investment.

Case Study 19: Power Sector Reform Experiences in Russia. 198

The wholesale energy market was fully liberalised in 2011 and covers much of European Russia, the Urals and Siberia. Since then most power has been sold and bought on a competitive basis through the central wholesale spot market. Energy prices generally reflected movements in underlying supply-demand fundamentals and short run marginal production costs driven largely by changes in upstream fuel costs. The Federal Antimonopoly Service provides independent objective and consistent supervision with incentive based economic regulation. Open access arrangements are in place for transmission and distribution networks. The Federal Grid Company has a major network development program that will improve regional power flows by 2020, but this is now informed by real detailed regional and grid exit point power flows, enabling solid projections of demand and a better basis for investment decisions.

Competition and innovation. Although Russia’s very successful 2008 privatisation brought several new entrants, the government still has considerable scope to diversify ownership and wholesale competition through further divestment as well as virtual power auctions or similar mechanisms to sell rights to the output of publicly owned generators. It can also strengthen market integration and effective competition supervision. Russia’s competitive wholesale spot market is one of the most successful components of the reform implemented to date.

Competitive retail markets are in an early phase of development in Russia. Although still concentrated in outmoded retail market structures, Russian policy makers have taken positive steps towards establishing the market rules and regulations needed to develop competitive and innovative retail markets. But much still depends on how effectively these rules and regulations are translated into commercial incentives and practical processes. While progress has been made to rebalance consumer tariffs since 2001, 10% of revenues are still subject to cross-subsidies concentrated in a relatively small part of total load. Residential tariffs still need to increase by 50-70% to address this.

Price reform remains essential for success. The Russian Federation has made considerable progress in rebalancing tariffs, but there is more to do, especially for regulated residential consumers. The presence of dominant ‘Guaranteeing Suppliers’ with local regulated residential consumers and universal supply obligation franchises remain an inherently unsustainable element. Price increases could be linked to growth in user capacity to pay while direct government welfare payments to regulated users should replace user-funded energy subsidies. At the same time, the government needs to keep pursuing supply-side reforms to help reduce the level of cost-reflective prices.

3.5.2 Opportunities and Prospects

Integrating consumer energy efficiency with supply side

North American utilities typically work in a regulated market context in which regulators oversee investments and operational performance including the performance of utility demand side management activities. Documents like the Californian Standard Practice Manual set out methods for evaluating the energy efficiency programme costs and both the energy and other benefits that accrue to consumers.
### 3.6. Energy Resource Sustainability

Energy resource sustainability addresses a range of issues including the cleaner use of fossil fuel resources (extraction, production, generation, transmission, and consumption) and the increased use of renewable energy. All these have implications to other sectors and resources including water, food, and land use, among others so that nexus issues need to be considered.

As mentioned elsewhere in this report, energy and climate objectives are closely linked, and a summary of the climate commitments of UNECE countries submitted under the Paris Agreement is presented in this section.

#### 3.6.1 Selected Issues and Country Responses

**Issue 1: Commitments to Reduce Energy Sector Greenhouse Gas Emissions**

CO₂ emissions from energy contributed 76% of total greenhouse gas emissions globally in 2010. In 2012, the UNECE region emitted 31.5% of global GHG emissions. At 32.1 Gt of CO₂ emitted, global energy-related CO₂ emissions were static for a third straight year in 2016. The global economy grew 3.1% in this same year, signalling a medium term decoupling of emissions growth and economic activity. This decoupling resulted from switches from coal to natural gas, improvements in energy efficiency, structural changes in the global economy, and increasing renewable power generation.

CO₂ emissions declined in the United States and China (the world’s two-largest energy users and CO₂ emitters), offsetting increases in most of the rest of the world, and were stable in Europe. The biggest drop came from the United States, where CO₂ emissions fell 3%, or 160 Mt, while the economy grew by 1.6%. The decline was driven by a surge in shale gas supply and renewable power displacing coal. Emissions in the United States last year were at their lowest level since 1992, yet the economy has grown by 80% since then.

Prior to COP21 in 2015, countries submitted their intended nationally determined contributions (INDCs) to define their voluntary contributions to mitigate climate change. These commitments are diverse, as they reflect local conditions and capabilities, and vary in scope, pledged pathway, conditionality, and additionality. Within the outcome document of COP21, the “Paris Agreement”, countries agreed to reduce GHG emissions to those consistent with well below 2°C temperature rise. As of 22 August 2017, 165 INDCs covering 192 parties (out of 197), and 155 parties have submitted their Nationally Determined Contributions (NDCs) to the UNFCCC Convention. The NDCs represent 96% of the Parties to the Convention, including the European Union and its member countries as one regional entity.

Within the UNECE region, as of 19 April 2017, all member States have submitted INDCs. Table 3.8 provides a simple overview of each member States’ submission of INDCs, the status of ratification, the reduction targets, and an analysis of energy key words.

---

* First NDC means the NDC is equal to the INDC submitted before COP21, but it has been ratified by the party.

** 1= Key word mentioned in (I)NDC.

**** Dates of ratification vary depending on the Member States. As of July 2017 two EU Member States, Czech Republic and The Netherlands, have not yet ratified the Paris Agreement.

***** Data only available for Serbia and Montenegro together.

****** Withdrawal announced on 1 June 2017.
From the (I)NDC submission by member States all except two countries (Belarus and Serbia) mention energy within their (I)NDC. Two thirds mention renewable energy, and almost three quarters emphasize energy efficiency. Energy access is only mentioned by a quarter of the (I)NDCs, reflecting the comparatively lower urgency of energy access within the UNECE region. In terms of emission reductions, the EU and its member states have already reduced their emission by 19% on 1990 levels while GDP has grown 44%. Per capita emissions have fallen from 12 tCO$_2$eq in 1990 to 9 tCO$_2$eq in 2012 and are projected to fall to around 6 tCO$_2$eq in 2030 (see also case study 20).206

### Case Study 20: The European Union’s Nationally Determined Contributions.

The European Union and its 28 Member States are committed to a binding target of at least 40% absolute domestic reductions in GHG emissions by 2030 compared to 1990 base year. The NDC is to be fulfilled jointly, as set out in the conclusions by the European Council of October 2014. The NDC covers emissions from Energy, Industrial processes and product use, Agriculture, Waste, Land Use, Land-Use Change and Forestry (set out in Decision 529/2013/EU)

The target represents a significant progression beyond its current undertaking of a 20% emission reduction commitment by 2020 compared to 1990 (which includes the use of offsets). It is in line with the European Union objective, in the context of necessary reductions according to the IPCC by developed countries as a group, to reduce its emissions by 80-95% by 2050 compared to 1990. The NDC plans no contribution from international credits.207

According to Eurostat, in 2015, greenhouse gas emissions in the European Union, including emissions from international aviation and indirect CO2 emissions, were down by 22.1% compared with 1990 levels. The European Union is thus expected to exceed its Europe 2020 target of reducing GHG emissions by 20% by 2020.208

The Paris Agreement is a success that nearly all countries submitted (I)NDCs based on the concept of “common but differentiated responsibilities”, as defined by UNFCCC.209

Since their submission, a range of analysis papers have been published to assess if (I)NDCs are sufficient to limit global warming to 2°C, or even 1.5°C. Results indicate that the combined mitigation actions in country submissions would only limit global warming to between 2.5 and 2.8°C (compared to current policies projections of 3.3 to 3.9°C).210

The analyses conclude that greater efforts are required by the global community to achieve the stated objectives. This conclusion is particularly true for the UNECE region with high emitting countries and sub-regions, particularly North America and Western and Central Europe, which needs to be reflected in future sustainable energy strategies.

Climate Action Tracker analysed if selected countries can achieve the commitments announced in their (I)NDCs.211 For example, it is expected that Canada, under its current policies, will miss its 2030 NDC target to reduce GHG emissions by 30% below 2005 levels in 2030 by a wide margin. However, the implementation of a national mandatory carbon-pricing plan that was announced in 2016, would represent a major step towards policies that could change this adverse outlook. With its current policies, the European Union is expected to come close in range of meeting its target of reducing emissions by 40% below 1990 levels by 2030. However, as mentioned above, this will not be sufficient to limiting warming to below 2°C. From the eastern part of the UNECE Region, Kazakhstan is recognized for its plans to transit into a greener future, though currently its implemented policies are not yet sufficient to meet its INDC target to reduce GHG emissions by 15% below 1990 levels by 2030.

Sources: United States EPA (2016); GMI (2017); United States EPA (2017).
It should be noted that data sets on methane in both the Coal and Oil & Gas sectors are incomplete and different analyses offer different values for CBM and CMM. Technologies for detecting and quantifying methane emissions, as well as standard national/regional methods for reporting them are available. However, their implementation is not always harmonised and in some cases it may be too complicated to make comparisons of the data.

With changing commitments following COP21, all data sets and projections need to be reviewed and updated in light of the current policies. However two conclusions can be drawn: (1) the scale of Coal Bed Methane in UNECE is vast, exceeding 12Tnm3, and (2) CMB and CMM offers, if properly managed, an access to abundant valuable resources and provide an opportunity for easily obtainable emission reductions. Case study 21 provides insight on Coal Seam Methane Recovery in Poland and Ukraine.

### Case Study 21: Coal Seam Methane Recovery: Examples from Poland and Ukraine.

**Poland**: 24% of mine methane is currently being captured by methane management systems in Poland. Nevertheless, 110 million m³ of methane was still vented to the atmosphere in 2014. Methane utilization has dropped slightly from 68% in 2013 to 66% in 2014.

With 930 Mm³/year methane bearing capacity, and 338 Mm³/year methane drainage, a potential 680 million m³ VAM (including 110Mm³ that is ready to manage Since 2010 there has been support for electricity produced from high efficiency cogeneration Primary Energy Saving > 10%).

**Ukraine**: In 2015, 35Mt of coal was mined in Ukraine (less than half the 2014 antebellum levels) with 562Mm³ per year of coal mine methane, of which 404Mm³ are extracted with ventilation and 28% or 158Mm³ by outgassing. In 2015 methane capture was undertaken in 2 mines.

### Issue 3: The Energy - Water - Land Nexus

Energy has significant connections to agriculture, water, and climate. The process of extracting and processing natural energy resources, the subsequent generation of power, and transmission and distribution via grids and pipelines has a significant impact on a variety of other economic and environmental processes and activities. These connections offer an opportunity for synergies to increase sustainability, but they could negatively affect competing sectors. Water captured for a hydropower dam may not be available for irrigation downstream and could impact river ecosystems. Warm water discharge from thermal power plants impacts fisheries and wildlife. The production of biofuels may lead to land competition for food production, binds water resources and leads to mono-cultures. On the other hand, agriculture is an energy-intense sector, with 4% of global electricity and 50mtoe of energy currently being used in irrigation pumping and desalination. Over the next 25 years, the amount of energy used in the water sector will more than double, mostly because of desalination projects that will account for 20% of water-related electricity demand by 2040. Large-scale water transfer projects and increasing demand for wastewater treatment also contribute to the water sector’s rising energy needs.

The connections and synergies between sectors are described as a nexus. A nexus offers opportunities to minimize resource input and waste, emission, and energy leakage by narrowing material and energy loops. The energy-water-agriculture nexus is highly relevant for the energy sector. Trans-boundary water basins represent a particular governance challenge – there are over 270 trans-boundary river basins in the world, covering approximately 60% of the globe’s freshwater flow and roughly 40% of the population. Additionally, there are an estimated 600 aquifers that are shared by two or more nations. How a river or aquifer is managed or used in one location can drastically affect other locations further up or downstream. Case study 22 on the Drina Basin, covering six UNECE countries, including Bosnia and Herzegovina, Montenegro, and Serbia, provides an analysis on the energy-food-water nexus and its challenges and opportunities for more sustainable resource management.

### Case Study 22: Drina River Basin Energy-Water-Food Nexus Solutions Assessment.

The Drina River, located in the Western Balkans and shared by Bosnia and Herzegovina, Montenegro and Serbia, is the main tributary of the Sava River, and groundwater represents the main source of water supply for communities in the basin. Surface water resources also support significant power generation (both hydropower and thermal power) that is key for the energy security of the three countries and also produces revenues from exports.

A participatory assessment of the intersectoral links, trade-offs and benefits in the water-food-energy-ecosystems nexus involving the energy, agriculture, water and environmental authorities of the three countries and other key stakeholders was carried out under the Convention on the Protection and Use of Transboundary Watercourses and International Lakes. The interactions of energy with other sectors, relevant for resource management, were jointly identified. Selected examples for each group of interlinkages are given below to illustrate possible solutions related to policy or technical measures, also determined in the process.
3.6.2 Opportunities and Prospects

Increasing international cooperation to increase ambitions to reduce greenhouse gas emissions

If countries do not act faster in the period to 2030 they will be obliged to make much greater reduction efforts in the period after 2025 to hold the temperature rise below 2°C above pre-industrial levels. Currently policies for sustainable energy tend to work in a disaggregated way. Separate energy efficiency, renewable energy and climate policies are led by different operational agencies. There is a need to integrate GHG mitigation potentials with the potentials for energy efficiency and renewable energy to develop a clearer understanding of the trade-offs and economically optimal investment paths available to countries in the UNECE region.

Exploring technology options to decarbonize fossil fuel based power generation

If the world is to constrain CO₂ emissions to levels consistent with a less than 2°C rise in global temperatures, then Carbon Capture and Storage (CCS) will need to contribute about one-sixth of needed CO₂ emission reductions in 2050, and 14 per cent of the cumulative emissions reductions between 2015 and 2050 compared to a business-as-usual approach. It is the only technology option other than energy efficiency and shifting the primary energy mix to lower carbon fuels that can deliver net emissions reductions at the required scale. The IPCC’s AR5 Synthesis Report estimated that without CCS the cost of climate mitigation would increase by 138%. Global CO₂ storage levels of at least one billion tonnes per year by 2030 need to be in place, and more thereafter. Delivering such an outcome will require collective commitment by governments and industry alike to fund CCS demonstration projects and development efforts in power and industrial applications at levels commensurate with the required abatement outcomes. Ensuring the availability of CCS will require regulatory and legislative support at all levels of government and international cooperation at project level so the necessary financing can be unlocked.
Opportunity: How carbon capture and storage in cleaner electricity production and through enhanced oil recovery could be used in reducing greenhouse gas emissions.\textsuperscript{225}

The UNECE Group of Experts on Cleaner Electricity Production from Fossil Fuels Coal Mine Methane (CMM) prepared recommendations for how CCS and CCS for Enhanced Oil Recovery (EOR) should be treated in a Post-Kyoto Protocol Agreement. After the approval of the recommendations by the UNECE Committee on Sustainable Energy, they were transmitted to the UNFCCC in 2014. The recommendations covert the following items:

- Policies on CCS/CCUS should have parity with other no carbon/low carbon technology regarding their climate mitigation potential, commensurate with the state of technological and infrastructure development.
- Governments should consider a broad array of fiscal instruments to encourage CCS/CCUS until carbon is properly and adequately priced. Capturing and storing CO\textsubscript{2} from all industrial sectors will be essential to reach climate goals. CCS/CCUS deployment will accelerate if governments work together to financially sponsor demonstration projects.
- Developed countries should be encouraged to invest in CCS/CCUS in developing countries.
- CCS developments need to be monitored and tracked globally so best practice guidance on CCS can be developed and disseminated.

Improved methane management in coal, oil and gas sector

According to the EPA, coal mining accounted for 8\% of total global anthropogenic methane emissions in 2010, and these emissions are projected to increase by 33\% to 784 million metric tons of carbon dioxide equivalent (Mt CO\textsubscript{2eq}) by 2030. The global abatement potential is projected to be 50 to 468 tCO\textsubscript{2eq} or 6 to 60\% of baseline emissions, in 2030. The cost-effective abatement potential (USD 0 break-even price) is 77.7 tCO\textsubscript{2eq} or 10\% of baseline.

The technological maximum potential (USD 100 + break-even price) is 467.6 tCO\textsubscript{2eq} or 60\% of baseline.

The technological maximum for emissions reduction potential in oil and gas is 1,219 million metric tons of carbon dioxide equivalent (Mt CO\textsubscript{2eq}), approximately 58\% of projected emissions in 2030. Because of the energy value of the methane captured, EPA estimates that 747 MtCO\textsubscript{2eq} or 40\% of the baseline emissions, can be cost-effectively reduced. Over 26\% of total abatement potential is achieved by adopting abatement measures in the oil and gas production segments.\textsuperscript{226}

Significant programmes to reduce the flaring of associated gas from oil extraction founded the global natural gas industry during the 1970s. Recovered coal seam methane can be used as a fuel and extraction methods for methane for coal, oil and gas extraction processes are mature; options to recover methane from coal seams include:

- Coal Bed Methane processes extract methane from unmined coal seams. The coal seams may still be mined in the future but this is largely dependent upon geological factors, such as coal depth and quality;
- Coal Mine Methane processes extract methane during mining activities as the coal is in the process of being extracted and thus emitting significant quantities of the gas;
- Abandoned Mine Methane processes recover methane from mines that have been closed as significant amounts of methane may remain trapped in the mine or may continue to be emitted from openings.

There is significant scope to transform fugitive methane emissions into useful energy resources while mitigating methane GHG. Many countries have coal seam methane management regimes in place. The United States Environmental Protection’s (US EPA) modelling outlines global marginal abatement cost curves for methane management but there is no up to date comprehensive evaluation of the potential for methane management programs and their capabilities yet.

The extensive switching of power production from coal to gas and solar in the United States highlights the role that methane resources could play in the energy transition. The increasing utilization of gas has raised the issue of fugitive emissions of methane from both conventional and shale gas production.

Taking into account revised estimates for fugitive methane emissions, recent lifecycle assessments indicate that specific GHG emissions are reduced by one half (on a per-kWh basis) when shifting from the current world-average coal fired power plant to a modern natural gas combined-cycle (NGCC) power plant.\textsuperscript{227} This reduction is the result of the lower carbon content of natural gas (15.3 grams of carbon per megajoule (gC/MJ) compared to, e.g., 26.2 gC/MJ for sub-bituminous coal) and the higher efficiency of combined-cycle power plants.\textsuperscript{228}

The priority for methane management is to monitor and record emissions accurately using the best monitoring and measurement technology and to assess the best solutions to minimize leaks and emissions. More efficient and effective methane management will offer direct economic benefits which include: decreasing negative health impacts, increasing workers’ safety and reducing global warming. However, more work is needed to demonstrate how methane options can advance the energy transition.

Recent progress in fracking technique, and methane management, Degasification and Ventilation Air Methane
In this context the UNECE Secretariat in consultation with the secretariats of the International Gas Union, the World Coal Association and the World Petroleum Council and other industry experts, has prepared and executed a survey on techniques and measures currently undertaken to measure, report, and verify (MRV) methane emissions in extractive industries. The data obtained from the survey shows that very few entities operating in the extractive industries do not monitor their gas emissions. Similarly, only few do not report the results, as such reporting is oftentimes mandated by law. However, the underlying reason for monitoring are diverse. While the primary purpose was “environment” and “law” for the oil and the gas industries, stakeholder forum the coal industry singled out “safety” as the main reason. More than half of all industries distinguish between methane and other hydrocarbon gases during the monitoring. In terms of continuity of measurements, results vary for sectors. 50% of coal mines measure continuously, as the gas in the mine is released into the working environment. For oil and gas (mid- and downstream), about a third of the companies measure continuously. Only the coal sector has a standardized approach on the control of CH₄ emissions. Responses to question #17 (image 10) indicate that methods for CH₄ emissions monitoring typically ARE mandated by law for global coal industry and are NOT for the other industrial sectors covered by the survey. Monitoring measures are not standardized across entities and sectors. With a vast resource of coal bed methane and scope to increase, the United Nations Economic Commission for Europe (UNECE) Committee on Sustainable Energy recommended that work be done to agree on common philosophies, standards, and technology for monitoring, recording, and reporting methane emissions at each stage of production, processing, storage, transmission, distribution, and use of fossil fuels, whether coal, oil, or natural gas, recognizing at the same time that case by case adaptation to specific situations might be necessary. Additionally, it was agreed there is a need to mitigate methane emissions, including identifying appropriate mechanisms for mobilizing needed resources, and to fund a detailed study on a common basis across the entire UNECE region. In response, the Committee requested that work be undertaken to assess baseline, benchmarking and scale of current methane emissions in the extractive industries, with the aim of giving clear guidance to practitioners and policy-makers.

### Opportunity: Best Practice Guidance for Effective Methane Drainage and Use in Coal Mines

The UNECE Group of Experts on Coal Mine Methane (CMM) has released the second edition of the Best Practice Guidance for Effective Methane Drainage and Use in Coal Mines. Since the first edition was published in 2010, the industry practice and regulations have evolved, and the second edition captures the most critical developments. The second edition also includes additional case studies that illustrate the application of the best practices in coalmines worldwide. The principles-based second edition of Best Practice Guidance does not replace national or international laws and regulations. Rather, it complements them through a holistic approach to safer and more effective methane management practices.

### Realizing synergies in the Energy-Water-Land Nexus

Understanding the social, economic and environmental diversity and potentials is at the heart of solutions for ecosystems with energy-water-land use nexus challenges. Often the solution lies in better understanding the diversity of needs in the region around the eco-system and the breadth of benefits that can be drawn from the ecosystem. Communities can then find ways to enable that diversity of outcomes from better management of the nexus relationships and dependencies in the eco-system.

To identify opportunities for increase resource sustainability while limiting negative impacts on connected sectors, a range of tools and approaches have been developed in the past. Tools like strategic environmental assessment (SEA) enable new insights into inter-sectoral synergies to address trade-offs and externalities in resource utilisation and trans-boundary issues. Besides facilitating potential inter-sectoral conflicts (e.g. likely impacts resulting from hydropower development on water resources or agriculture soil in downstream sections), SEA also provides an opportunity for a wide range of stakeholders (environmental and health authorities, businesses, public) to provide their feedback on proposed development in a given sector or area. Thus, efficient application of SEA can streamline development and implementation of specific projects by addressing issues that are difficult to grasp at the project level (especially large-scale and cumulative effects); and by providing an early warning on problems to be solved when designing the projects and carrying out relevant permitting procedure including EIA. This in turn expands the scope of economic sustainable energy potentials and maximises system resilience by opening up multiple options for resources, rather than singular reliance on traditional resources and technology. Countries and regional communities can extract more value from a wider and more sustainable range of resource options, increase economic trade in resources, to improve system sustainability and resilience.

Several tools and approaches have been developed to assess intersectoral links and dynamics including energy at different
scales and for different purposes, and could be considered for detailing a scoping level assessment of the kind applied in the river basins referred to in Box “Good Practices and Policies for Inter-Sectoral Synergies to Develop Renewable Energy: Opportunities in hydropower more sustainable”. These include: (1) dialogues; (2) mapping; (3) scenarios; (4) extended systems analysis; and (5) institutional analysis. Several more detailed nexus analysis tools and efforts focus on accounting for the inputs and outputs of resources when delivering services, indicating where and how resources are linked, as well as how those linkages will compound direct and indirect demands. Each have an explicit focus on water, energy and land-use activities and how those are linked, and the most appropriate one can be selected depending on the purpose of the analysis.

An example of an integrated resource assessment tool is the INOGATE RESMAP Geospatial mapping for sustainable energy investment project, presented in below box. While this tool currently covers only Georgia, Armenia, Azerbaijan, Moldova, it highlights the scope for a richer understanding of options to fully deliver GHG reductions and SDG objectives and the scope of energy, industrial processes and product use, agriculture, waste, land use, land-use change and forestry options that need to be understood and managed to deliver SDG objectives in full.

### Opportunity: Geospatial Mapping for Sustainable Energy

The INOGATE RESMAP online geospatial mapping platform demonstrates the value at stake from wind and solar investment to stakeholders in Georgia, Armenia, Azerbaijan and Moldova. It enables assessment of the theoretical, ecological and economically viable wind and solar energy resource maps, using highly granular data (at least 10km square resolution). Infrastructure and constraint maps on a web-based ‘GeoExplorer’ map enable labelling, zoom, measurement functions, scroll down boxes and relevant information tools. This enables stakeholders (investors, policy makers, equipment suppliers) the location, amount (MW and GWh/year) and Net Present Value of the economically viable wind and solar resource available in their country, at different combinations of capital cost; investment discount rate and power purchase tariff, thereby determining the value at stake. Mapping existing reference projects, wind and solar resource will assist dialogue between policy makers, investors and other stakeholders and a better optimisation of resources constraints and objectives.

A series of policies and technology already exist that can help reduce water and energy demand, and ease potential chokepoints in the water-energy nexus. These include integrating energy and water policymaking, co-locating energy and water infrastructure, utilising the energy embedded in wastewater, using alternative sources of water for energy and improving the efficiency of both sectors.

### Opportunity: Good Practices and Policies for Inter-Sectoral Synergies to Develop Renewable Energy: Opportunities in making hydropower more sustainable

Renewable energy can play a strong role in helping to achieve better management of resources within the water-energy-food-ecosystems nexus. The nexus approach itself presents an opportunity to strengthen the actions aimed at achieving the SDGs. So far, four nexus assessments have been completed in the Alazani/Ganykh (Azerbaijan, Georgia), Sava (Bosnia and Herzegovina, Croatia, Montenegro, Serbia, and Slovenia), Syr Darya (Kazakhstan, Kyrgyzstan, Tajikistan, Uzbekistan7), and Drina Basins (Bosnia and Herzegovina, Montenegro and Serbia).

The assessments provide the input to develop policy recommendations, including measures that could facilitate renewable energy deployment, which is more sustainable and accounts for the nexus trade-offs between the energy, water and food sectors and the ecosystems. The nexus assessments demonstrate that depending on the context, diverse solutions to externalities from hydropower development and making renewable energy more sustainable can be identified, ranging from technical measures to information and governance. Some selected examples about such solutions are given below (with a focus on energy sector measures):

- The Sava and Drina River Basins - Develop hydropower sustainably and integrate other renewable energies; coordinate operation of hydropower plants (for flood control, for energy system benefits, ensuring environmental flow); and development of new capacities ideally with a basin-wide strategy, taking into account the trade-offs with other water uses and the environment;
- The Alazani/Ganykh River Basin - Facilitate access to modern energy sources and energy trade; minimize impacts from new hydropower development; apply catchment management to control erosion to limit impacts on infrastructure;
- The Syr Darya River Basin - Promote restoring the regional grid and vitalizing energy market; improve efficiency in energy generation, transmission and use; improve efficiency in water use (especially in agriculture).

The basin cases show that through regional and transboundary cooperation in both the energy sector and in water management – across sectors – negative intersectoral and environmental impacts can be reduced and synergic beneficial actions have more impact.
Identifying sub-regional challenges in the UNECE region

Attainment of the objectives of SDG 7 is falling short in the UNECE region. Many good examples exist, but overall countries need to accelerate efforts in order to achieve all three pillars of SDG 7: energy access, energy efficiency and renewable energy.

While many of the energy challenges in the region are similar to those elsewhere in the world, the region has specific climatic, economic, environmental and political circumstances and the implications are found in inefficient use of energy, power cuts, increasing energy costs, and unsustainable and unaffordable heating in winter.

Moving beyond the UNECE regional level, sub-regional analysis provides useful insights behind the aggregated UNECE results. Although the region as a whole has tremendous untapped potential for all forms of renewable energy, so far renewable energy sources contribute only 11% of TFC. While this share and the underlying progress rate is insufficient to achieve the global target of 18% renewable energy share in 2030, Southeast Europe has achieved the 2030 target already (26%). This is mirrored by sub-regions at the lower end of the spectrum, including the Russian Federation (3.5%), Eastern Europe (5.2%), and Caucasus, and Central Asia (7.4%).

Looking deeper into the sub-regions with low renewable energy shares, in 2015, 17 UNECE member States from these sub-regions only received USD 400 million investments. This represents only about 0.2% of the global total investment in renewable energy technologies, a decrease from 0.5% in 2014. An absence of new investments is noticeable in the Caucasus, Central Asia, and Southeast Europe.

Regarding energy efficiency results, the UNECE CAGR energy intensity of -2.0% for 2012-2014 differs significantly on sub-regional level. North America improved its energy intensity from 5.9 to 5.8 MJ/USD, at a rate of -0.5% per year (CAGR). Southeast Europe's energy intensity declined from 5.0 to 4.6 MJ/USD, at a -4.5% CAGR. The sub-region Caucasus, Central Asia, Eastern Europe and the Russian Federation shows the highest energy intensity rate with 7.2 MJ/USD (~3.8% CAGR). Compared with the required CAGR of -2.6% to achieve the 2030 target, different progress rates on sub-regional level need to be considered when planning how to address the gaps towards the 2030 Agenda.

Although the region has achieved universal household electrification in terms of physical access, ageing infrastructure, a lack of supply diversity and increasing tariffs lead to poor power quality and, for some, energy poverty. This situation is particularly acute during the cold winter months of the Northern hemisphere, and disproportionately affects poor and rural populations. As a result, some consumers have reverted to local sources of solid fuels for cooking and heating, and others to electricity with off-grid diesel generators.

At present, some countries export large quantities of fossil fuels as part of their economic model and feature some of the world’s highest levels of energy intensity. The number of countries and the number of people whose national incomes and livelihood depend on fossil energy is important and will remain so over the outlook period. Many countries struggle to provide reliable and affordable energy for their own citizens. Numerous market barriers, often linked to subsidised energy prices, impede the introduction of new, efficient energy technology. Lack of access to basic energy services and frequent disruption of power supply are of particular concern in the Caucasus and Central Asia.

Many of the same countries have high carbon footprints due to a legacy of high energy intensity and high energy inefficiency in industry and buildings. Energy losses from old infrastructure and dilapidated networks are significant. Carbon intensity has remained flat.

Conclusions

Collaborating on the 2017 GTF and its regional interpretation with internationally respected partners and the other four Regional Commissions has been an extraordinary opportunity for UNECE to gain insights into regional concerns and reflect on progress of SDG 7 implementation in more detail. This report seeks to raise awareness about a number of issues, notably the extraordinary potential that the UNECE region offers with regards to energy efficiency and renewable energy development and deployment. It will be very useful for subsequent activities of UNECE and its partners, serving as a baseline.

From mere tracking progress on SDG 7, this report is has turned into a step towards tracking progress beyond SDG 7. It has become evident that the current approach would benefit from refinements. Relevant indicators should reflect a holistic
approach and address the challenges that countries face as systems become more complex and needs more urgent. Taking demand for energy services as the basis of such an approach, a broader set of indicators naturally emerges.

Work is just beginning. UNECE is committed to driving sustainable energy systems further and would like to work with regional partners to shed further light on successful and replicable case studies and business models that can lift barriers and will inspire others to follow.

The report would benefit from more extensive consultation with countries. This requires more time and resources to exchange views with experts in countries, most often in national languages or with interpretation. Rather than embarking quickly on another GTF process, benefit might derive from a further analysis of all existing findings and data and their interpretation and a careful consultation process with countries to develop a set of needs in the context of quality of life.

**Recommendations**

There is no common view in the UNECE region of what sustainable energy is or how to attain it. Apart from the global challenges of the Agenda 2030 and addressing climate change, countries in the UNECE have divergent economic development, resource availability and energy mixes embedded in today’s national energy strategies. Each country sets its national energy strategy based on its unique perspectives on sustainable development, environmental protection, poverty alleviation, climate change mitigation, quality of life, and the like. As a consequence, multiple national approaches and outcomes can be found. Tracking progress towards sustainable energy forms an important basis for the further development of strategies and policies. Based on this report, the following recommendations to improve progress tracking initiatives emerge:

- Current indicators derive from the existing data gathering and reporting infrastructure that have emerged from the energy system of the past. In order to inform policies to accelerate the transition to an energy system that can support sustainable development, it will be necessary to develop appropriate indicators adapted to the system of the future, adapt data gathering systems, and build the required capacities to collect, analyse, track and report new data and indicators. At a minimum, new indicators should embrace the nexus areas with water, food, and climate, track investments in clean energy and enlarge the chosen energy indicators to include other forms of energy. For energy, it is critical to think in terms of a wholly interconnected, complex system, in which supply, demand, conversion, transport/transmission interact freely and flexibly. This perspective applies within regions, subregions but also between regions and economic sectors.

- Indicators to track energy for sustainable development beyond those for SDG 7 show that increased efforts are required throughout the energy system. Attaining the objectives of the 2030 Agenda will require full engagement of the private sector to transform energy. As a consequence, it is essential to monitor progress on energy for sustainable development in ways that reflect the cross-cutting interconnections among the SDGs and that involve the private sector in more integrated ways.

- While the costs of renewable energy may be falling, the cost of integrating intermittent sources of energy into the grid is not. The challenge goes beyond financing investments and involves approaching a sustainable energy mix from a different angle and applying broad thinking to a net zero-carbon energy system. Every technology has an important role to play in the future energy system over the medium term, not only energy efficiency and renewable energy, but also advanced fossil technology and carbon capture, use and storage. Choices must be economically and socially rational for each country and be made in the broader context of an economy as a whole. The integration should consider quality of life and not just access to energy.

- Growing awareness and interest in renewable energy resources has highlighted a need to normalize the way in which renewable energy potential is classified, reported and managed. A shared framework to evaluate energy resources could also provide a foundation for investors, regulators and governments to implement renewable energy projects.

- Work needs to continue to reinforce investment appetite in key countries in the region in renewable energy. A number of platforms and tools exist to bring the financial sector in contact with technology providers and policy makers. There is equally great potential in the transformation of large industrial complexes. In the UNECE region, there are a number of such complexes, where mining, power generation, metallurgy, manufacturing and shipping facilities are integrated into dense, interrelated businesses. Value might derive from developing replicable and transformation business models, seeking the expertise on a variety of innovative technology and policy aspects. This way, energy efficiency and renewable energy aspects can be integrated into the clean-up of existing fossil structures and thus can contribute to the development of large innovation-led, socially and environmentally responsible projects.

- As noted elsewhere in this report, the UNECE membership is highly diverse. Dividing the UNECE countries in seven sub-regions proves useful to identify sub-regional challenges and progress made so far, while considering national contexts with neighbouring countries.
Chapter IV: Conclusions and Recommendations

Additional sub-regional reports analysing progress and experiences more deeply and in a targeted manner could supplement global and regional GTF reports and provide an implementable action agenda to countries.

Limitations and outlook

Key limitations of this report include the availability of comparable, verified and current data from all countries within the timeframe of the report, not only for the agreed SDG 7 indicators, but also as a basis to broaden the set of indicators to track energy for sustainable development.

The data gathering and reporting infrastructure that exists today has emerged and evolved over many years, and changes and improvements to this system require extensive consultation, adaptation, and capacity development support, which are ongoing, but will take more time to realize in practice. Tracking important pillars such as the carbon intensity of energy, per capita carbon emissions, are difficult across the region due to missing data or differences in reporting approaches.

This report has suggested a number of new paradigms for indicators for the future, whether related to quality of service or holistic systems analysis. There is merit in considering what indicators would point to a future in which energy for sustainable development is assured. Once a concise set of indicators has been identified, it will be necessary to establish data gathering infrastructure to ensure that data are available to populate a new set of indicators credibly.

The energy industry has succeeded in raising quality of life around the world, most notably in the advanced economies, but access and affordability remain challenges. New approaches from a services perspective will allow those without access to energy to leapfrog existing technology and systems and benefit from innovation and falling technology costs. Changing the energy industry to a service configuration involves changing a utility’s (or service provider’s) business model to one of maximizing the margins between the revenues received for services provided (for example, indoor comfort or mobility) and the costs of providing the services (through, for example, efficiency investments). Realizing the potential will require careful reconsideration of and readiness to revisit the existing regulatory, policy, technical, and organizational infrastructure of energy.

# Units of Measurement

- °C  Degree Celsius
- bbl  Barrel
- bcm  Billion cubic metres
- Bn  Billion
- Bnm³  Billion cubic meters
- EJ  Exajoules (One exajoule equals one quintillion (10¹⁸) joules)
- gC  Grams of carbon
- Gt  Gita tons
- GW  Gigawatt
- GWh  Gigawatt-hour (equals 1 million kilowatt-hours)
- kWh  Kilowatt-hour
- kWp  Kilowatt-peak
- m³  Cubic meters
- MJ  Megajoules (One megajoule equals one million (10⁶) joules)
- Mm³  Million cubic meters
- Mt  Million tons
- MtCO₂eq  Million tons carbon dioxide equivalent
- mtoe  Million tons oil equivalent
- MW  Megawatt
- MWe  Megawatt electric
- MWh  Megawatt hour
- PJ  Petajoules (One petajoule equals one quadrillion (10¹⁵) joules)
- t  Tons
- TJ  Terajoules (One terajoule equals one trillion (10¹²) joules)
- Tn  Trillion
- Tnm³  Trillion cubic meters
- TWh  Terawatt hour (equals 1 billion kilowatt-hours)
Glossary

**Compound Annual Growth Rate (CAGR), in %**

CAGR of primary/final energy intensity between two years. Represents the average annual growth rate during the period. Negative values represent improvements in energy intensity (less energy is used to produce one unit of economic output), while positive numbers indicate declining energy intensity (more energy is used to produce one unit of economic output).

**Energy Intensity, in MJ/2011 PPP USD**

Primary energy intensity is used as a proxy indicator for energy efficiency. It is calculated as the ratio of TPES to GDP measured at PPP in constant 2011 USD (MJ/2011 PPP USD): Energy intensity is an indication of how much energy is used to produce one unit of economic output. Lower ratio indicates that less energy is used to produce one unit of output (GTF 2017 definition).

**Gross Domestic Product (GDP), in 2011 PPP USD**

GDP (in 2011 PPP USD) is the sum of gross value added by all resident producers in the economy plus any product taxes and minus any subsidies not included in the value of the products. It is calculated without making deductions for depreciation of fabricated assets or for depletion and degradation of natural resources. GDP is measured at purchasing power parity at constant 2011 USD (GTF 2017 definition).

**Kilowatt Peak (kWp)**

Kilowatt peak stands for peak power. This value specifies the output power achieved by a solar module under full solar radiation (under set Standard Test Conditions). Solar radiation of 1,000 watts per square meter is used to define standard conditions. Peak power is also referred to as “nominal power” by most manufacturers. Since it is based on measurements under optimum conditions, the peak power is not the same as the power under actual radiation conditions. In practice, this will be approximately 15-20% lower due to the considerable heating of the solar cells. Source: SMA Solar Technology AG (2011).

**Levelized Cost of Electricity (LCOE), in USD-Cents/kWh**

Levelized cost of electricity (LCOE) represents the kilowatt-hour cost of building and operating a power generation plant over an assumed financial life and duty cycle (Solar Mango definition).

**Own Production, as ratio +/-1**

Dividing the total primary energy supply of a country by its energy production gives an indication on the level of self-sufficiency (or dependency) of a country (IEA Energy Atlas definition).

**Total Energy Production**

Production is the production of primary energy, i.e. hard coal, lignite, peat, crude oil, NGL, natural gas, combustible renewable energy and waste, nuclear, hydro, geothermal, and solar and the heat from heat pumps that is extracted from the ambient environment. Production is calculated after removal of impurities (e.g. sulphur from natural gas) (IEA definition).

**Total Final Energy Consumption (TFC), in Mtoe**

Sum of energy consumption by the different end-use sectors, excluding non-energy uses of fuels. TFC is broken down into energy demand in the following sectors: industry, transport, residential, services, agriculture, and others. It excludes international marine and aviation bunkers, except at world level where it is included in the transport sector (IEA definition).

**Total Primary Energy Supply (TPES), in Mtoe**

TPES is made up of: Production + Imports - Exports - International marine bunkers - International aviation bunkers +/- Stock changes (IEA definition).

**Renewable Energy**

Total Renewable Energy includes modern and traditional energy. Traditional energy stands for solid biomass when consumed in the residential sector in non-Organisation for Economic Cooperation and Development (OECD) countries. It includes the following categories in International Energy Agency (IEA) statistics: primary solid biomass, charcoal and non-specified primary biomass and waste. Modern Energy includes all types of technology including solar, wind, biomass, geothermal, hydro, liquid biofuels, biogas, marine, and renewable wastes (GTF 2017 definition).

</tbody>
</table>

Note: The “own production index” is the same as IEA’s “self-sufficiency index”. Dividing the TPES of a country by its own energy production gives an indication of a country’s energy balance. TPES is the sum of production and imports less exports and stock change. A value above 1 indicates a net exporter, below 1 means a net importer.

Source: IEA World Energy Balances.
Annex III. Energy for Sustainable Development Indicators and GTF Methodology

History and Methodology: SDG 7 (SEforALL) indicators used for the Global GTF Report

The methodology applied for the Global GTF Report can be found at http://gtf.esmap.org/methodology

Beyond SDG 7 Indicators: Information needs and challenges for Sustainable Development

The energy systems structure used in this report is intended to complement the GTF SE4ALL reporting framework and extend from it to offer a structured set of insights into the challenges and opportunities to improving the sustainability, societal wellbeing, economic and environmental implications of energy systems in UNECE member countries. The content provided in this report goes beyond the SDG 7 indicators in order to provide perspectives beyond aggregate framework indicators. The ability to do this depends on the quality and competence of underlying data systems.

Methodological issues

In many countries a number of agencies collect energy, activity and related social and environmental data.

Regional and global assessment like this report rely on the data gathering and management processes operated by a number of key agencies that have developed leading capabilities and relationships that enable consistency in data definitions, quality management, data warehousing and publication. The ‘data specialisations’ are recognized, and also characterized by cooperation and data validation across the data managing agencies: World Bank and OECD economic activity data; UN population and human activity data; WHO health and wellbeing data; IEA energy data. While individual countries, and agencies specializing on one or another aspect of global activities also publish data, their perspectives and data validation processes tend to occur within a limited perspective of the global data managers.

Data differences

Differences in data derive from three main areas:

● Data frameworks and definitional differences.
● Data sources with different perspectives.
● Accounting misalignments.

Consistent data standards IEA Stats, UN data definitions etc.: Where differences in data occur this is always an opportunity to explore the cause and nature of underlying differences in data systems.

Missing data

The data gathering and reporting infrastructure that exists today has emerged and evolved over many years. This report has suggested a number of new paradigms for indicators for the future, whether related to quality of service or holistic systems analysis. There would be merit in considering what indicators would point to a future in which energy for sustainable development is assured. Once a concise set of indicators has been identified, it will be necessary to establish data gathering infrastructure to ensure that data are available to populate a new set of indicators credibly.
# Annex IV. Draft List of Indicators to Track Energy for Sustainable Development

## Table A.3: Draft List of Indicators and Areas for Possible Indicators to Measure Energy for Sustainable Development to Achieve the 2030 Agenda.

<table>
<thead>
<tr>
<th>Pillars</th>
<th>Suggested Indicators (or areas for indicator formulation)</th>
</tr>
</thead>
</table>
| **Energy**         | 7.1.1 Proportion of Population with Primary Reliance on Clean Cooking Fuels and Technology*  
|                    | 7.1.2 Proportion of Population with Access to Electricity*  
|                    | Affordability, expressed as share of household income spent on energy**  
|                    | Suggested areas to formulate additional indicators:  
|                    | Reliability and quality of electricity access**  
|                    | Number of hours of access to electricity per day (outage rates)  
|                    | Technical quality (frequency, voltage)  
|                    | Number of turnoffs by type of consumer  
|                    | Number of households with access to main grid  
|                    | Time required to fix disruptions  
|                    | Number of households with generators  
|                    | Loss of GDP through interrupted supply (VOLL)  
|                    | Transmission losses  
|                    | Energy Poverty, encompassing access to and quality of heating and cooling**  
| **Energy Access**  | 7.2.1 Renewable Energy Share in Total Final Energy Consumption (TFC)*  
|                    | Share of modern / traditional renewable energy in TFC**  
|                    | Share of renewable energy in Total Primary Energy Supply (TPES)**  
|                    | Additions of renewable energy installed capacity**  
|                    | Investments in renewable energy**  
|                    | Share of renewable energy in bus-bar energy (e.g. post combustion but pre transmission & distribution losses)  
| Renewable Energy   | Installed reliable renewable energy capacity per capita  
|                    | Renewable energy by type of output (electricity, liquids, heat)  
|                    | Ratio of renewable energy (capacity, production/consumption) to total electricity (capacity, production/consumption)  
|                    | Share of renewable energy expressed in terms of Total Primary Energy Requirements (i.e., taking into account the actual non-renewable primary energy required to provide the same final RE)  
|                    | Number of people with access to RE  
|                    | Terms of access of renewable producers to networks  
|                    | Share of renewable energy in installed reliable capacity (versus generation)  
|                    | Cost of producing 1kWh from solar PV / wind /other renewable energy (under consideration of distribution losses with a view towards improving the network)  
|                    | Installed energy storage (batteries (including EV’s), pumped storage, phase change materials, other technologies)

* SDG7 indicator / indicator used in global 2017 GTF.
** Recommended indicator to be used to track Energy for Sustainable Development within the 2030 Agenda for Sustainable Development.

All remaining: Suggestions made (1) in the context of a workshop “Tracking Progress on Energy for Sustainable Development: Data and Indicators”, held in Astana on 14 June 2017, as part of the Eighth Forum on Energy for Sustainable Development, (2) by expert reviser, partly based on E. Worrell et al. (1997): Energy intensity in the iron and steel industry: a comparison of physical and economic indicators. In: Energy Policy, Vol. 25, 1997; (3) as part of the preparatory work to develop a Policy Brief “Indicators and Data for Energy for Sustainable Development” as input paper for the High-Level Political Forum 2018.
### TABLE A.4: Potential Indicators within Different Elements of the Energy System.

<table>
<thead>
<tr>
<th>System Element</th>
<th>Insights</th>
<th>Potential Indicators</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Consumer service quality</strong></td>
<td>There is a need to move beyond simple notions of ‘access’ and ‘energy poverty’ to real metrics for end use service quality, entitlement and access in households and businesses, while accommodating diversity in resources, expectations and needs. Importantly how these contribute to SDG outcome goals.</td>
<td>Systematic tracking of: 1. Achieved end-use service quality against basic welfare norms. 2. Affordability of end use service quality (the cost of the service attained rather than the unit price of energy)</td>
</tr>
<tr>
<td><strong>End-use efficiency</strong></td>
<td>There is a need to move beyond naive energy intensity to real energy efficiency indicators, with a concatenated structure of indicators that also highlight structure and activity within households and businesses.</td>
<td>Systematic tracking of: 1. Changes in household size, occupancy, and efficiency of key end use applications in households. 2. Changes in economic structure, end use efficiency and value added in industry and commerce. 3. Changes in modal and vehicle structure, activity and end use efficiency in transport.</td>
</tr>
<tr>
<td><strong>Distributed cost-reflective utilities</strong></td>
<td>There is a need to identify how utilities can better incentivise consumer demand responsiveness and end-use efficiency as T&amp;D utilities shift from being energy distributors to become capacity managers of diverse central and distributed energy producers.</td>
<td>Systematic tracking of: 1. Changes in the actual performance of central supply systems, distributed and end-use renewable energy, within competent life cycle analytical frameworks.</td>
</tr>
<tr>
<td><strong>Supply system innovation and sustainability</strong></td>
<td>There is a need to understand how supply side policies and practices can evolve a more sustainable and economically efficient supply system.</td>
<td>Systematic tracking of: 1. Changes in supply system value and performance within competent life cycle analytical frameworks.</td>
</tr>
<tr>
<td><strong>Resource sustainability</strong></td>
<td>There is a need to understand how diversifying the resource mix, economic trade, and managing environmental nexus impacts can enable a more resilient and sustainable energy system.</td>
<td>Systematic tracking of: 1. Metrics for separate and integrated resource (energy water, land, and air) system resilience. 2. Changes in resource (energy water, land, and air) system value and performance within competent life cycle analytical frameworks. 3. Metrics for nexus dynamics.</td>
</tr>

References

1. The Global Tracking Framework reports have been published in 2013, 2015, and 2017, following the initiation of the Sustainable Energy for All (SEforALL) initiative in December 2010. The third report in 2017 links tracking of SEforALL with the tracking of SDG 7, with involvement of the five Regional Commissions. The global and five regional reports are published online: http://gtf.esmap.org

2. Target 7.1 and 7.3 are the same as the SEforALL targets 1 and 3. Target 7.2 differs as the SEforALL renewables target aims to “double the share of renewable energy in the global energy mix”.

3. GDP, PPP (constant 2011 international USD).

4. As defined by the International Energy Agency (IEA), total primary energy supply (TPES) (in terajoules [TJ]) is production plus net imports minus international marine and aviation bunkers plus/minus stock changes. Data sources: Energy balances from the IEA, supplemented by UN Statistical Division for countries not covered by IEA.

7. The sub-regions in this report differ from the 2017 GTF which divided the UNECE region in four sub-regions. While the sub-regions Western and Central Europe, Southeast Europe and North America remain the same, the 2017 GTF sub-region “Central Asia, Caucasus, Eastern Europe, Israel, Russian Federation, and Turkey” was further split into four regions Caucasus, Central Asia including Turkey, Eastern Europe including Israel, Southeast Europe, and the Russian Federation.

10. Data presented here are based on 2014, following the tracking period of 2012–2014 for the 2017 GTF report. At the writing of the global GTF report, no more recent data were available. The results presented in this report are hence limited with a view towards more recent developments across the energy sector.

11. No data available for Andorra, Liechtenstein, Monaco, and San Marino.

19. SE4ALL tracking is replaced by SDG 7 tracking which are the same indicators. The methodology and data sources for the GTF indicators can be reviewed in Annex IV.

20. Total final energy consumption (TFC) is the sum of energy consumption by the different end-use sectors, excluding non-energy uses of fuels. TFC is broken down into energy demand in the following sectors: industry, transport, residential, services, agriculture, and others. It excludes international marine and aviation bunkers, except at world level where it is included in the transport sector. Data sources: Energy balances from IEA, supplement-ed by United Nations Statistical Division for countries not covered by IEA.

26. Definition as used in GTF 2017: Primary energy intensity is the ratio of TPES to GDP measured at PPP in constant 2011 USD (MJ/2011 PPP$). Throughout this document references to USD use 2011 values calculated on the basis of purchasing power parity (PPP).

27. The 1% increase in energy intensity in 2010 resulted from the global financial crisis as economic activity decreased slightly faster than energy demand.

28. One exajoule equals 1018 (one quintillion) joules.

31. As reported in World Bank et al. (2017a).

32. The ranking of Iceland as an energy-intense economy shows the shortcomings of using energy intensity as an indicator for energy efficiency. The high reliance on geothermal electricity with efficiency ratings of 10% is the reason for its high energy intensity, despite numerous energy saving programmes http://energyatlas.iea.org/#/tellmap/-297203538/1.

34. Economidou et al. (2016).

35. As reported in World Bank et al. (2017a).

36. Within the GTF, renewable energy consumption includes “renewable energy consumption of all technology: hydro, biomass, wind, solar, liquid biofuels, biogas, geothermal, marine and renewable wastes”. Modern renewable energy consumption is defined as “total renewable energy consumption minus traditional consumption/use of biomass. It covers all forms of renewable energy directly measured, including wind, hydro, solar, geothermal, marine, biogas, liquid biofuel, renewable energy waste, and modern biomass”. Traditional renewable energy consumption is defined as “final consumption of traditional uses of biomass. Biomass uses are considered traditional when biomass is consumed in the residential sector in non-Organisation for Economic Co-operation and Development (OECD) countries. It includes the following categories in IEA statistics: primary solid biomass, charcoal and non-specified primary biomass and waste.”

37. As reported in World Bank et al. (2017a).

41. According to the GTF 2017, modern renewable energy consumption includes solar, wind, biomass, geothermal, hydro, liquid biofuels, biogas, marine, and renewable wastes, without traditional energy which is defined as solid biomass when consumed in the residential sector in non-Organisation for Economic Cooperation and Development (OECD) countries.

42. IEA (2016e): Key World Energy Statistics.

43. The renewable power capacity data shown in these tables represents the maximum net generating capacity of power plants and other installations that use renewable energy sources to produce electricity (IRENA Statistics). This includes Hydro (small and large), pumped storage and mixed plants, marine energy, geothermal, solar photovoltaic (PV), concentrated solar power (CSP), wind (on/off shore), and bioenergy (sodlas biomass, renewable waste, biogas, and liquid biofuels).

57. A limited number of combustion tests point to efficiencies similar to other controlled combustion stoves; generally above 60% and up to 72%.

58. KAPSARC (-).

59. KAPSARC (-).

73. IEA (2016d):  
71. Data Source: European Commission Joint Research Center (2014): GHG (CO2, CH4, N2O, F-gases) emission time series 1990-2012 per region/country. This includes all GHG emissions within the energy sector, excluding LULUCF: CO2, CH4, N2O, and aggregate F-gases in t CO2 equivalent. The energy sector includes: energy industries, manufacturing industries and construction, transport, fugitive emissions from fuels, CO2 transport and storage, as well as other and non-specified sectors. Note: The reporting and review requirements for GHG inventories are different for Annex I and non-Annex I Parties within the Kyoto Protocol. 
70. This includes all GHG emissions within the energy sector, excluding LULUCF: CO2, CH4, N2O, and aggregate F-gases in t CO2 equivalent. The energy sector includes: energy industries, manufacturing industries and construction, transport, fugitive emissions from fuels, CO2 transport and storage, as well as other and non-specified sectors. The reporting and the review requirements for GHG inventories are different for Annex I and non-Annex I Parties within the Kyoto Protocol.

77. DENA (2010). Another possible data source is the Emission Database for Global Atmospheric Research (EDGAR4) which has been developed jointly by the European Commission’s Joint Research Centre (JRC) and the PBL Netherlands Environmental Assessment Agency. EDGAR4 provides global anthropogenic emissions of greenhouse gases CO2, CH4, N2O, HFCs, PFCs and SF6 and of precursor gases and air pollutants CO, NOx, NMVOC, SO2 and the aerosols PM10, PM2.5, BC, OC, per source category, at country level. See edgar.jrc.ec.europa.eu. However, only total greenhouse gas emissions are given, with no specific data for the energy sector only. Another option are the emission data from the Global Carbon Project http://cdiac.ornl.gov/GCP/  
70. IPCC (2014a).  
69. Another possible data source is the Emission Database for Global Atmospheric Research (EDGAR4) which has been developed jointly by the European Commission’s Joint Research Centre (JRC) and the PBL Netherlands Environmental Assessment Agency. EDGAR4 provides global anthropogenic emissions of greenhouse gases CO2, CH4, N2O, HFCs, PFCs and SF6 and of precursor gases and air pollutants CO, NOx, NMVOC, SO2 and the aerosols PM10, PM2.5, BC, OC, per source category, at country level. See edgar.jrc.ec.europa.eu. However, only total greenhouse gas emissions are given, with no specific data for the energy sector only. Another option are the emission data from the Global Carbon Project http://cdiac.ornl.gov/GCP/ 
68. IEA (2015b): 
66. CO2 emissions from fuel combustion only. 
65. Data source: IEA World Energy Balances. Calculations exclude emission data for Andorra, Liechtenstein, Monaco and San Marino. Data include only CO2 emissions from fossil fuel combustion, not any other GHG emissions and fugitive emissions such as CH4 emission from coal mining. For comparison: in 2012, the UNECE share in global GHG emissions was 31.5% (Source: World Bank World Development indicator). 
64. IEA (2015b): 
63. Fluorinated gases (F-gases) are a family of man-made gases used in a range of industrial applications. Because they do not damage the atmospheric ozone layer, they are often used as substitutes for ozone-depleting substances. However, F-gases are powerful greenhouse gases, with a global warming effect up to 23 000 times greater than carbon dioxide (CO2), and their emissions are rising strongly. Source: European Commission (2017c): Fluorinated greenhouse gases. https://ec.europa.eu/clima/policies/f-gas_en  

98. Out of the 18 countries that reported a rate below 98 % in 2014. The 36 countries that reached a rate above 98% in 2014 are not considered in the projections.

100. As energy consumers save on energy cost through energy efficiency, they may spend their savings on other energy-intensive activities, or increase their demand for the new service, thereby counteracting the potential savings of energy. This is called the rebound effect. In: IEA (2011): Energy Efficiency Policy and Carbon Pricing. https://www.iea.org/publications/freePublications/publication/EE_Carbon_Pricing.pdf.

105. UNECE (2013).

115. The GFEI is a partnership of the IEA, UNEP and other organisations, and works to secure real improvements in fuel efficiency, and the maximum deployment of existing fuel economy technology in vehicles across the world. See website for more information: https://www.globalfueleconomy.org/.

117. GFEI (2016).

122. IEA (2012).

125. For more information about the activities of the UNECE Group of Experts on Energy Efficiency please visit https://www.unece.org/energyefficiency.html.

Endnotes

130. BPIE et al. (2016).
135. UNECE has not reviewed these policies, as this is a significant task and well beyond the scope of this report.
136. The 2006 EU Directive on Energy End-Use Efficiency and Energy Services (Energy Services Directive) requires Member States to submit NEEAP in 2007, 2011 and 2014. In the first NEEAP each Member State should have adopted an overall national indicative savings target for end-use sectors of 9% or higher, to be achieved in 2016, with an intermediate target for 2010.
138. Through the implementation of PEEREA, the Energy Charter provides its member countries with a menu of good practices and a forum in which to share experiences and policy advice on energy efficiency issues. There are two types of reviews conducted by the Energy Charter in its member countries: regular monitoring based on a standard review format and in-depth energy efficiency reviews.
139. Approximately every four years, the policies of individual member countries are reviewed in-depth by a team of peers led by the IEA. The country review are available online: https://www.iea.org/publications/countryreviews/
143. “Distributed,” “decentralized” or “off-grid” generation (or energy) is defined as the “installation and operation of electric power generation units connected directly to the distribution network or connected to the network on the customer side of the meter” with the purpose to “provide a source of active electric power. This type of more local generation is different from the common system of centralized supply including large-scale fossil fuel fired power plants, and hydro power, as well as large-scale renewable energy such as off-shore wind, which require transmission lines to transport the power produced over vast distances.
153. Pelkmans et al. (2014).
155. Kilowatt peak stands for peak power. This value specifies the output power achieved by a Solar module under full solar radiation (under set Standard Test Conditions). Solar radiation of 1,000 watts per square meter is used to define standard conditions. Peak power is also referred to as “nominal power” by most manufacturers. Since it is based on measurements under optimum conditions, the peak power is not the same as the power under actual radiation conditions. In practice, this will be approximately 15-20% lower due to the considerable heating of the solar cells. Source: SMA Solar Technology AG (2011).

World Bank et al. (2017a).
The current rate of progress is insufficient to achieve the three pillars of SDG7 by 2030. Despite advances in electricity access, challenges of energy affordability and quality persist. Improving energy efficiency is the most important enabler for sustainable energy. The uptake and investments into renewable energy vary vastly across the UNECE region. Indicators need to be refined to reflect the real imperatives of energy for sustainable development.
